Abstract

The System Administrator's Guide documents relevant information regarding the deployment, configuration, and administration of Red Hat Enterprise Linux 7. It is oriented towards system administrators with a basic understanding of the system. To expand your expertise, you might also be interested in the Red Hat System Administration I (RH124), Red Hat System Administration II (RH134), Red Hat System Administration III (RH254), or RHCSA Rapid Track (RH199) training courses. If you want to use Red Hat Enterprise Linux 7 with the Linux Containers functionality, see Product Documentation for Red Hat Enterprise Linux Atomic Host. For an overview of general Linux Containers concept and their current capabilities implemented in Red
Hat Enterprise Linux 7, see Overview of Containers in Red Hat Systems. The topics related to containers management and administration are described in the Red Hat Enterprise Linux Atomic Host 7 Managing Containers guide.

# System Administrator’s Guide

## PART IV. INFRASTRUCTURE SERVICES

### CHAPTER 9. MANAGING SERVICES WITH SYSTEMD
- 9.1. INTRODUCTION TO SYSTEMD
- 9.2. MANAGING SYSTEM SERVICES
- 9.3. WORKING WITH SYSTEMD TARGETS
- 9.4. SHUTTING DOWN, SUSPENDING, AND HIBERNATING THE SYSTEM
- 9.5. CONTROLLING SYSTEMD ON A REMOTE MACHINE
- 9.6. CREATING AND MODIFYING SYSTEMD UNIT FILES
- 9.7. ADDITIONAL RESOURCES

### CHAPTER 10. CONFIGURING A SYSTEM FOR ACCESSIBILITY
- 10.1. CONFIGURING THE BRLTTY SERVICE
- 10.2. SWITCH ON ALWAYS SHOW UNIVERSAL ACCESS MENU
- 10.3. ENABLING THE FESTIVAL SPEECH SYNTHESIS SYSTEM

### CHAPTER 11. OPENSSH
- 11.1. THE SSH PROTOCOL
- 11.2. CONFIGURING OPENSSH
- 11.3. OPENSSH CLIENTS
- 11.4. MORE THAN A SECURE SHELL
- 11.5. ADDITIONAL RESOURCES

### CHAPTER 12. TIGERVNC
- 12.1. VNC SERVER
- 12.2. SHARING AN EXISTING DESKTOP
- 12.3. VNC VIEWER
- 12.4. ADDITIONAL RESOURCES

## PART V. SERVERS

### CHAPTER 13. WEB SERVERS
- 13.1. THE APACHE HTTP SERVER

### CHAPTER 14. MAIL SERVERS
- 14.1. EMAIL PROTOCOLS
- 14.2. EMAIL PROGRAM CLASSIFICATIONS
- 14.3. MAIL TRANSPORT AGENTS
- 14.4. MAIL DELIVERY AGENTS
- 14.5. MAIL USER AGENTS
- 14.6. ADDITIONAL RESOURCES

### CHAPTER 15. FILE AND PRINT SERVERS
- 15.1. SAMBA
- 15.2. FTP
- 15.3. PRINT SETTINGS

### CHAPTER 16. CONFIGURING NTP USING THE CHRONY SUITE
- 16.1. INTRODUCTION TO THE CHRONY SUITE

PART I. BASIC SYSTEM CONFIGURATION

This part covers basic system administration tasks such as keyboard configuration, date and time configuration, managing users and groups, and gaining privileges.
CHAPTER 1. SYSTEM LOCALE AND KEYBOARD CONFIGURATION

The system locale specifies the language settings of system services and user interfaces. The keyboard layout settings control the layout used on the text console and graphical user interfaces.

These settings can be made by modifying the `/etc/locale.conf` configuration file or by using the `localectl` utility. Also, you can use the graphical user interface to perform the task; for a description of this method, see Red Hat Enterprise Linux 7 Installation Guide.

1.1. SETTING THE SYSTEM LOCALE

System-wide locale settings are stored in the `/etc/locale.conf` file, which is read at early boot by the `systemd` daemon. The locale settings configured in `/etc/locale.conf` are inherited by every service or user, unless individual programs or individual users override them.

The basic file format of `/etc/locale.conf` is a newline-separated list of variable assignments. For example, German locale with English messages in `/etc/locale.conf` looks as follows:

```
LANG=de_DE.UTF-8
LC_MESSAGES=C
```

Here, the `LC_MESSAGES` option determines the locale used for diagnostic messages written to the standard error output. To further specify locale settings in `/etc/locale.conf`, you can use several other options, the most relevant are summarized in Table 1.1, “Options configurable in `/etc/locale.conf`”. See the `locale(7)` manual page for detailed information on these options. Note that the `LC_ALL` option, which represents all possible options, should not be configured in `/etc/locale.conf`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LANG</td>
<td>Provides a default value for the system locale.</td>
</tr>
<tr>
<td>LC_COLLATE</td>
<td>Changes the behavior of functions which compare strings in the local alphabet.</td>
</tr>
<tr>
<td>LC_CTYPE</td>
<td>Changes the behavior of the character handling and classification functions and the multibyte character functions.</td>
</tr>
<tr>
<td>LC_NUMERIC</td>
<td>Describes the way numbers are usually printed, with details such as decimal point versus decimal comma.</td>
</tr>
<tr>
<td>LC_TIME</td>
<td>Changes the display of the current time, 24-hour versus 12-hour clock.</td>
</tr>
<tr>
<td>LC_MESSAGES</td>
<td>Determines the locale used for diagnostic messages written to the standard error output.</td>
</tr>
</tbody>
</table>

Table 1.1. Options configurable in `/etc/locale.conf`
1.1.1. Displaying the Current Status

The `localectl` command can be used to query and change the system locale and keyboard layout settings. To show the current settings, use the `status` option:

```
localectl status
```

**Example 1.1. Displaying the Current Status**

The output of the previous command lists the currently set locale, keyboard layout configured for the console and for the X11 window system.

```
~$ localectl status
  System Locale: LANG=en_US.UTF-8
  VC Keymap: us
  X11 Layout: n/a
```

1.1.2. Listing Available Locales

To list all locales available for your system, type:

```
localectl list-locales
```

**Example 1.2. Listing Locales**

Imagine you want to select a specific English locale, but you are not sure if it is available on the system. You can check that by listing all English locales with the following command:

```
~$ localectl list-locales | grep en_
en_AG
en_AG.utf8
en_AU
en_AU.iso88591
en_AU.utf8
en_BW
en_BW.iso88591
en_BW.utf8
```

*output truncated*

1.1.3. Setting the Locale

To set the default system locale, use the following command as `root`:

```
localectl set-locale LANG=locale
```

Replace `locale` with the locale name, found with the `localectl list-locales` command. The above syntax can also be used to configure parameters from Table 1.1, “Options configurable in `/etc/locale.conf`”.
Example 1.3. Changing the Default Locale

For example, if you want to set British English as your default locale, first find the name of this locale by using `list-locales`. Then, as root, type the command in the following form:

```
~]# localectl set-locale LANG=en_GB.utf8
```

1.1.4. Making System Locale Settings Permanent when Installing with Kickstart

When Red Hat Enterprise Linux is installed with the Red Hat Kickstart installation method, setting of the system locales might not be persistent after an upgrade of the operating system.

When the `%packages` section of the Kickstart file includes the `--instLang` option, the `_install_langs` RPM macro is set to the particular value for this installation, and the set of installed locales is adjusted accordingly. However, this adjustment affects only this installation, not subsequent upgrades. If an upgrade reinstallss the glibc package, the entire set of locales is upgraded instead of only the locales you requested during the installation.

To avoid this, make the choice of locales permanent. You have these options:

- If you have not started the Kickstart installation, modify the Kickstart file to include instructions for setting RPM macros globally by applying this procedure: Procedure 1.1, “Setting RPM macros during the Kickstart installation”

- If you have already installed the system, set RPM macros globally on the system by applying this procedure: Procedure 1.2, “Setting RPM macros globally”

Procedure 1.1. Setting RPM macros during the Kickstart installation

- Modify the `%post` section of the Kickstart file:

```
LANG=en_US
echo "%_install_langs $LANG" > /etc/rpm/macros.language-conf
awk '$NF==0 && !done){print
"override_install_langs='$LANG'"; done=1}{print}' \
< /etc/yum.conf > /etc/yum.conf.new
mv /etc/yum.conf.new /etc/yum.conf
```

Procedure 1.2. Setting RPM macros globally

1. Create the RPM configuration file at `/etc/rpm/macros.language-conf` with the following contents:

```
%_install_langs LANG
```

LANG is the value of the `instLang` option.

2. Update the `/etc/yum.conf` file with:

```
override_install_langs=LANG
```
1.2. CHANGING THE KEYBOARD LAYOUT

The keyboard layout settings enable the user to control the layout used on the text console and graphical user interfaces.

1.2.1. Displaying the Current Settings

As mentioned before, you can check your current keyboard layout configuration with the following command:

```bash
localectl status
```

Example 1.4. Displaying the Keyboard Settings

In the following output, you can see the keyboard layout configured for the virtual console and for the X11 window system.

```
$ localectl status
  System Locale: LANG=en_US.utf8
    VC Keymap: us
    X11 Layout: us
```

1.2.2. Listing Available Keymaps

To list all available keyboard layouts that can be configured on your system, type:

```bash
localectl list-keymaps
```

Example 1.5. Searching for a Particular Keymap

You can use `grep` to search the output of the previous command for a specific keymap name. There are often multiple keymaps compatible with your currently set locale. For example, to find available Czech keyboard layouts, type:

```
$ localectl list-keymaps | grep cz
  cz
  cz-cp1250
  cz-lat2
  cz-lat2-prog
  cz-qwerty
  cz-us-qwertz
  sunt5-cz-us
  sunt5-us-cz
```

1.2.3. Setting the Keymap

To set the default keyboard layout for your system, use the following command as `root`:

```bash
localectl set-keymap map
```
Replace \textit{map} with the name of the keymap taken from the output of the \texttt{localectl list-keymaps} command. Unless the \texttt{--no-convert} option is passed, the selected setting is also applied to the default keyboard mapping of the X11 window system, after converting it to the closest matching X11 keyboard mapping. This also applies in reverse, you can specify both keymaps with the following command as \texttt{root}:

\begin{verbatim}
localectl set-x11-keymap \textit{map}
\end{verbatim}

If you want your X11 layout to differ from the console layout, use the \texttt{--no-convert} option.

\begin{verbatim}
localectl --no-convert set-x11-keymap \textit{map}
\end{verbatim}

With this option, the X11 keymap is specified without changing the previous console layout setting.

\textbf{Example 1.6. Setting the X11 Keymap Separately}

Imagine you want to use German keyboard layout in the graphical interface, but for console operations you want to retain the US keymap. To do so, type as \texttt{root}:

\begin{verbatim}
~\$\$ localectl --no-convert set-x11-keymap de
\end{verbatim}

Then you can verify if your setting was successful by checking the current status:

\begin{verbatim}
~\$\$ localectl status
  System Locale: LANG=de\_DE.UTF-8
  VC Keymap: us
  X11 Layout: de
\end{verbatim}

Apart from keyboard layout (\textit{map}), three other options can be specified:

\begin{verbatim}
localectl set-x11-keymap \textit{map} \textit{model} \textit{variant} \textit{options}
\end{verbatim}

Replace \textit{model} with the keyboard model name, \textit{variant} and \textit{options} with keyboard variant and option components, which can be used to enhance the keyboard behavior. These options are not set by default. For more information on X11 Model, X11 Variant, and X11 Options see the \texttt{kbd(4)} man page.

\section*{1.3. ADDITIONAL RESOURCES}

For more information on how to configure the keyboard layout on Red Hat Enterprise Linux, see the resources listed below:

\textbf{Installed Documentation}

- \texttt{localectl(1)} – The manual page for the \texttt{localectl} command line utility documents how to use this tool to configure the system locale and keyboard layout.

- \texttt{loadkeys(1)} – The manual page for the \texttt{loadkeys} command provides more information on how to use this tool to change the keyboard layout in a virtual console.

\textbf{See Also}
● **Chapter 5, Gaining Privileges** documents how to gain administrative privileges by using the `su` and `sudo` commands.

● **Chapter 9, Managing Services with systemd** provides more information on `systemd` and documents how to use the `systemctl` command to manage system services.
CHAPTER 2. CONFIGURING THE DATE AND TIME

Modern operating systems distinguish between the following two types of clocks:

- A real-time clock (RTC), commonly referred to as a hardware clock, (typically an integrated circuit on the system board) that is completely independent of the current state of the operating system and runs even when the computer is shut down.

- A system clock, also known as a software clock, that is maintained by the kernel and its initial value is based on the real-time clock. Once the system is booted and the system clock is initialized, the system clock is completely independent of the real-time clock.

The system time is always kept in Coordinated Universal Time (UTC) and converted in applications to local time as needed. Local time is the actual time in your current time zone, taking into account daylight saving time (DST). The real-time clock can use either UTC or local time. UTC is recommended.

Red Hat Enterprise Linux 7 offers three command line tools that can be used to configure and display information about the system date and time: the timedatectl utility, which is new in Red Hat Enterprise Linux 7 and is part of systemd; the traditional date command; and the hwclock utility for accessing the hardware clock.

2.1. USING THE TIMEDATECTL COMMAND

The timedatectl utility is distributed as part of the systemd system and service manager and allows you to review and change the configuration of the system clock. You can use this tool to change the current date and time, set the time zone, or enable automatic synchronization of the system clock with a remote server.

For information on how to display the current date and time in a custom format, see also Section 2.2, “Using the date Command”.

2.1.1. Displaying the Current Date and Time

To display the current date and time along with detailed information about the configuration of the system and hardware clock, run the timedatectl command with no additional command line options:

```
timedatectl
```

This displays the local and universal time, the currently used time zone, the status of the Network Time Protocol (NTP) configuration, and additional information related to DST.

Example 2.1. Displaying the Current Date and Time

The following is an example output of the timedatectl command on a system that does not use NTP to synchronize the system clock with a remote server:

```
$ timedatectl
    Local time: Mon 2016-09-16 19:30:24 CEST
    Universal time: Mon 2016-09-16 17:30:24 UTC
    Timezone: Europe/Prague (CEST, +0200)
    NTP enabled: no
    NTP synchronized: no
    RTC in local TZ: no
    DST active: yes
```
IMPORTANT

Changes to the status of \texttt{chrony} or \texttt{ntpd} will not be immediately noticed by \texttt{timedatectl}. If changes to the configuration or status of these tools is made, enter the following command:

```
~]# systemctl restart systemd-timesd.service
```

### 2.1.2. Changing the Current Time

To change the current time, type the following at a shell prompt as \texttt{root}:

```
timedatectl set-time \texttt{HH:MM:SS}
```

Replace \texttt{HH} with an hour, \texttt{MM} with a minute, and \texttt{SS} with a second, all typed in two-digit form.

This command updates both the system time and the hardware clock. The result is similar to using both the \texttt{date --set} and \texttt{hwclock --systohc} commands.

The command will fail if an \texttt{NTP} service is enabled. See Section 2.1.5, “Synchronizing the System Clock with a Remote Server” to temporarily disable the service.

**Example 2.2. Changing the Current Time**

To change the current time to 11:26 p.m., run the following command as \texttt{root}:

```
~]# timedatectl set-time 23:26:00
```

By default, the system is configured to use UTC. To configure your system to maintain the clock in the local time, run the \texttt{timedatectl} command with the \texttt{set-local-rtc} option as \texttt{root}:

```
timedatectl set-local-rtc \texttt{boolean}
```

To configure your system to maintain the clock in the local time, replace \texttt{boolean} with \texttt{yes} (or, alternatively, \texttt{y}, \texttt{true}, \texttt{t}, or \texttt{1}). To configure the system to use UTC, replace \texttt{boolean} with \texttt{no} (or, alternatively, \texttt{n}, \texttt{false}, \texttt{f}, or \texttt{0}). The default option is \texttt{no}.

### 2.1.3. Changing the Current Date

To change the current date, type the following at a shell prompt as \texttt{root}:

```
timedatectl set-time \texttt{YYYY-MM-DD}
```
Replace *YYYY* with a four-digit year, *MM* with a two-digit month, and *DD* with a two-digit day of the month.

Note that changing the date without specifying the current time results in setting the time to 00:00:00.

**Example 2.3. Changing the Current Date**

To change the current date to 2 June 2017 and keep the current time (11:26 p.m.), run the following command as root:

```
~ $ timedatectl set-time 2017-06-02 23:26:00
```

**2.1.4. Changing the Time Zone**

To list all available time zones, type the following at a shell prompt:

```
timedatectl list-timezones
```

To change the currently used time zone, type as root:

```
timedatectl set-timezone time_zone
```

Replace *time_zone* with any of the values listed by the `timedatectl list-timezones` command.

**Example 2.4. Changing the Time Zone**

To identify which time zone is closest to your present location, use the `timedatectl` command with the `list-timezones` command line option. For example, to list all available time zones in Europe, type:

```
~ $ timedatectl list-timezones | grep Europe
Europe/Amsterdam
Europe/Andorra
Europe/Athens
Europe/Belgrade
Europe/Berlin
Europe/Bratislava
...
```

To change the time zone to *Europe/Prague*, type as root:

```
~ $ timedatectl set-timezone Europe/Prague
```

**2.1.5. Synchronizing the System Clock with a Remote Server**

As opposed to the manual adjustments described in the previous sections, the `timedatectl` command also allows you to enable automatic synchronization of your system clock with a group of remote servers using the NTP protocol. Enabling NTP enables the `chronyd` or `ntpd` service, depending on which of them is installed.
The NTP service can be enabled and disabled using a command as follows:

```
timedatectl set-ntp boolean
```

To enable your system to synchronize the system clock with a remote NTP server, replace `boolean` with `yes` (the default option). To disable this feature, replace `boolean` with `no`.

Example 2.5. Synchronizing the System Clock with a Remote Server

To enable automatic synchronization of the system clock with a remote server, type:

```
~]# timedatectl set-ntp yes
```

The command will fail if an NTP service is not installed. See Section 16.3.1, “Installing chrony” for more information.

2.2. USING THE DATE COMMAND

The `date` utility is available on all Linux systems and allows you to display and configure the current date and time. It is frequently used in scripts to display detailed information about the system clock in a custom format.

For information on how to change the time zone or enable automatic synchronization of the system clock with a remote server, see Section 2.1, “Using the `timedatectl` Command”.

2.2.1. Displaying the Current Date and Time

To display the current date and time, run the `date` command with no additional command line options:

```
date
```

This displays the day of the week followed by the current date, local time, abbreviated time zone, and year.

By default, the `date` command displays the local time. To display the time in UTC, run the command with the `--utc` or `-u` command line option:

```
date --utc
```

You can also customize the format of the displayed information by providing the `+"format"` option on the command line:

```
date +"format"
```

Replace `format` with one or more supported control sequences as illustrated in Example 2.6, “Displaying the Current Date and Time”. See Table 2.1, “Commonly Used Control Sequences” for a list of the most frequently used formatting options, or the `date(1)` manual page for a complete list of these options.

Table 2.1. Commonly Used Control Sequences
<table>
<thead>
<tr>
<th>Control Sequence</th>

<tr>
<td>%S</td>
<td>The second in the SS format (for example, 24).</td>
</tr>
<tr>
<td>%d</td>
<td>The day of the month in the DD format (for example, 16).</td>
</tr>
<tr>
<td>%m</td>
<td>The month in the MM format (for example, 09).</td>
</tr>
<tr>
<td>%Y</td>
<td>The year in the YYYY format (for example, 2016).</td>
</tr>
<tr>
<td>%Z</td>
<td>The time zone abbreviation (for example, CEST).</td>
</tr>
<tr>
<td>%F</td>
<td>The full date in the YYYY-MM-DD format (for example, 2016-09-16). This option is equal to %Y-%m-%d.</td>
</tr>
<tr>
<td>%T</td>
<td>The full time in the HH:MM:SS format (for example, 17:30:24). This option is equal to %H:%M:%S</td>
</tr>
</tbody>
</table>

**Example 2.6. Displaying the Current Date and Time**

To display the current date and local time, type the following at a shell prompt:

```
$ date
Mon Sep 16 17:30:24 CEST 2016
```

To display the current date and time in UTC, type the following at a shell prompt:

```
$ date --utc
Mon Sep 16 15:30:34 UTC 2016
```

To customize the output of the `date` command, type:

```
$ date +"%Y-%m-%d %H:%M"
2016-09-16 17:30
```

**2.2.2. Changing the Current Time**

To change the current time, run the `date` command with the `--set` or `-s` option as root:

```
date --set HH:MM:SS
```

Replace HH with an hour, MM with a minute, and SS with a second, all typed in two-digit form.

By default, the `date` command sets the system clock to the local time. To set the system clock in UTC,
run the command with the \-ut\c or \-u\ command line option:

```
date --set HH:MM:SS --utc
```

### Example 2.7. Changing the Current Time

To change the current time to 11:26 p.m., run the following command as root:

```
~\# date --set 23:26:00
```

#### 2.2.3. Changing the Current Date

To change the current date, run the date command with the --set or -s option as root:

```
date --set YYYY-MM-DD
```

Replace **YYYY** with a four-digit year, **MM** with a two-digit month, and **DD** with a two-digit day of the month.

Note that changing the date without specifying the current time results in setting the time to 00:00:00.

### Example 2.8. Changing the Current Date

To change the current date to 2 June 2017 and keep the current time (11:26 p.m.), run the following command as root:

```
~\# date --set "2017-06-02 23:26:00"
```

### 2.3. USING THE hwclock COMMAND

hwclock is a utility for accessing the hardware clock, also referred to as the Real Time Clock (RTC). The hardware clock is independent of the operating system you use and works even when the machine is shut down. This utility is used for displaying the time from the hardware clock. hwclock also contains facilities for compensating for systematic drift in the hardware clock.

The hardware clock stores the values of: year, month, day, hour, minute, and second. It is not able to store the time standard, local time or Coordinated Universal Time (UTC), nor set the Daylight Saving Time (DST).

The hwclock utility saves its settings in the /etc/adjtime file, which is created with the first change you make, for example, when you set the time manually or synchronize the hardware clock with the system time.
NOTE

In Red Hat Enterprise Linux 6, the \texttt{hwclock} command was run automatically on every system shutdown or reboot, but it is not in Red Hat Enterprise Linux 7. When the system clock is synchronized by the Network Time Protocol (NTP) or Precision Time Protocol (PTP), the kernel automatically synchronizes the hardware clock to the system clock every 11 minutes.

For details about NTP, see Chapter 16, \textit{Configuring NTP Using the chrony Suite} and Chapter 17, \textit{Configuring NTP Using ntpd}. For information about PTP, see Chapter 18, \textit{Configuring PTP Using ptp4l}. For information about setting the hardware clock after executing \texttt{ntpdate}, see Section 17.18, “Configuring the Hardware Clock Update”.

2.3.1. Displaying the Current Date and Time

Running \texttt{hwclock} with no command line options as the \texttt{root} user returns the date and time in local time to standard output.

\texttt{hwclock}

Note that using the \texttt{--utc} or \texttt{--localtime} options with the \texttt{hwclock} command does not mean you are displaying the hardware clock time in UTC or local time. These options are used for setting the hardware clock to keep time in either of them. The time is always displayed in local time. Additionally, using the \texttt{hwclock --utc} or \texttt{hwclock --local} commands does not change the record in the \texttt{/etc/adjtime} file. This command can be useful when you know that the setting saved in \texttt{/etc/adjtime} is incorrect but you do not want to change the setting. On the other hand, you may receive misleading information if you use the command an incorrect way. See the \texttt{hwclock(8)} manual page for more details.

Example 2.9. Displaying the Current Date and Time

To display the current date and the current local time from the hardware clock, run as \texttt{root}:

\begin{verbatim}
~\]\# hwclock
Tue 15 Apr 2017 04:23:46 PM CEST -0.329272 seconds
\end{verbatim}

CEST is a time zone abbreviation and stands for Central European Summer Time.

For information on how to change the time zone, see Section 2.1.4, “Changing the Time Zone”.

2.3.2. Setting the Date and Time

Besides displaying the date and time, you can manually set the hardware clock to a specific time.

When you need to change the hardware clock date and time, you can do so by appending the \texttt{--set} and \texttt{--date} options along with your specification:

\texttt{hwclock --set --date "dd mmm yyyy HH:MM"}

Replace \texttt{dd} with a day (a two-digit number), \texttt{mmm} with a month (a three-letter abbreviation), \texttt{yyyy} with a year (a four-digit number), \texttt{HH} with an hour (a two-digit number), \texttt{MM} with a minute (a two-digit number).
At the same time, you can also set the hardware clock to keep the time in either UTC or local time by adding the --utc or --localtime options, respectively. In this case, UTC or LOCAL is recorded in the /etc/adjtime file.

**Example 2.10. Setting the Hardware Clock to a Specific Date and Time**

If you want to set the date and time to a specific value, for example, to "21:17, October 21, 2016", and keep the hardware clock in UTC, run the command as root in the following format:

```
~]# hwclock --set --date "21 Oct 2016 21:17" --utc
```

### 2.3.3. Synchronizing the Date and Time

You can synchronize the hardware clock and the current system time in both directions.

- Either you can set the hardware clock to the current system time by using this command:

  ```
  hwclock --systohc
  ```

  Note that if you use NTP, the hardware clock is automatically synchronized to the system clock every 11 minutes, and this command is useful only at boot time to get a reasonable initial system time.

- Or, you can set the system time from the hardware clock by using the following command:

  ```
  hwclock --hctosys
  ```

When you synchronize the hardware clock and the system time, you can also specify whether you want to keep the hardware clock in local time or UTC by adding the --utc or --localtime option. Similarly to using --set, UTC or LOCAL is recorded in the /etc/adjtime file.

The `hwclock --systohc --utc` command is functionally similar to `timedatectl set-local-rtc false` and the `hwclock --systohc --local` command is an alternative to `timedatectl set-local-rtc true`.

**Example 2.11. Synchronizing the Hardware Clock with System Time**

To set the hardware clock to the current system time and keep the hardware clock in local time, run the following command as root:

```
~]# hwclock --systohc --localtime
```

To avoid problems with time zone and DST switching, it is recommended to keep the hardware clock in UTC. The shown Example 2.11, “Synchronizing the Hardware Clock with System Time” is useful, for example, in case of a multi boot with a Windows system, which assumes the hardware clock runs in local time by default, and all other systems need to accommodate to it by using local time as well. It may also be needed with a virtual machine; if the virtual hardware clock provided by the host is running in local time, the guest system needs to be configured to use local time, too.

### 2.4. ADDITIONAL RESOURCES
For more information on how to configure the date and time in Red Hat Enterprise Linux 7, see the resources listed below.

**Installed Documentation**

- `timedatectl(1)` – The manual page for the `timedatectl` command line utility documents how to use this tool to query and change the system clock and its settings.
- `date(1)` – The manual page for the `date` command provides a complete list of supported command line options.
- `hwclock(8)` – The manual page for the `hwclock` command provides a complete list of supported command line options.

**See Also**

- Chapter 1, *System Locale and Keyboard Configuration* documents how to configure the keyboard layout.
- Chapter 5, *Gaining Privileges* documents how to gain administrative privileges by using the `su` and `sudo` commands.
- Chapter 9, *Managing Services with systemd* provides more information on systemd and documents how to use the `systemctl` command to manage system services.
CHAPTER 3. MANAGING USERS AND GROUPS

The control of users and groups is a core element of Red Hat Enterprise Linux system administration. This chapter explains how to add, manage, and delete users and groups in the graphical user interface and on the command line, and covers advanced topics, such as creating group directories.

3.1. INTRODUCTION TO USERS AND GROUPS

While users can be either people (meaning accounts tied to physical users) or accounts that exist for specific applications to use, groups are logical expressions of organization, tying users together for a common purpose. Users within a group share the same permissions to read, write, or execute files owned by that group.

Each user is associated with a unique numerical identification number called a user ID (UID). Likewise, each group is associated with a group ID (GID). A user who creates a file is also the owner and group owner of that file. The file is assigned separate read, write, and execute permissions for the owner, the group, and everyone else. The file owner can be changed only by root, and access permissions can be changed by both the root user and file owner.

Additionally, Red Hat Enterprise Linux supports access control lists (ACLs) for files and directories which allow permissions for specific users outside of the owner to be set. For more information about this feature, see Chapter 4, Access Control Lists.

Reserved User and Group IDs
Red Hat Enterprise Linux reserves user and group IDs below 1000 for system users and groups. By default, the User Manager does not display the system users. Reserved user and group IDs are documented in the setup package. To view the documentation, use this command:

```
cat /usr/share/doc/setup*/uidgid
```

The recommended practice is to assign IDs starting at 5,000 that were not already reserved, as the reserved range can increase in the future. To make the IDs assigned to new users by default start at 5,000, change the UID_MIN and GID_MIN directives in the /etc/login.defs file:

```
UID_MIN                  5000
GID_MIN                  5000
```

For users created before you changed UID_MIN and GID_MIN directives, UIDs will still start at the default 1000.

Even with new user and group IDs beginning with 5,000, it is recommended not to raise IDs reserved by the system above 1000 to avoid conflict with systems that retain the 1000 limit.

3.1.1. User Private Groups

Red Hat Enterprise Linux uses a user private group (UPG) scheme, which makes UNIX groups easier to manage. A user private group is created whenever a new user is added to the system. It has the same name as the user for which it was created and that user is the only member of the user private group.
User private groups make it safe to set default permissions for a newly created file or directory, allowing both the user and the group of that user to make modifications to the file or directory.

The setting which determines what permissions are applied to a newly created file or directory is called a umask and is configured in the /etc/bashrc file. Traditionally on UNIX-based systems, the umask is set to 022, which allows only the user who created the file or directory to make modifications. Under this scheme, all other users, including members of the creator's group are not allowed to make any modifications. However, under the UPG scheme, this “group protection” is not necessary since every user has their own private group. See Section 3.3.5, “Setting Default Permissions for New Files Using umask” for more information.

A list of all groups is stored in the /etc/group configuration file.

3.1.2. Shadow Passwords

In environments with multiple users, it is very important to use shadow passwords provided by the shadow-utils package to enhance the security of system authentication files. For this reason, the installation program enables shadow passwords by default.

The following is a list of the advantages shadow passwords have over the traditional way of storing passwords on UNIX-based systems:

- Shadow passwords improve system security by moving encrypted password hashes from the world-readable /etc/passwd file to /etc/shadow, which is readable only by the root user.
- Shadow passwords store information about password aging.
- Shadow passwords allow to enforce some of the security policies set in the /etc/login.defs file.

Most utilities provided by the shadow-utils package work properly whether or not shadow passwords are enabled. However, since password aging information is stored exclusively in the /etc/shadow file, some utilities and commands do not work without first enabling shadow passwords:

- The chage utility for setting password aging parameters. For details, see the Password Security section in the Red Hat Enterprise Linux 7 Security Guide.
- The gpasswd utility for administrating the /etc/group file.
- The usermod command with the -e, --expiredate or -f, --inactive option.
- The useradd command with the -e, --expiredate or -f, --inactive option.

3.2. MANAGING USERS IN A GRAPHICAL ENVIRONMENT

The Users utility allows you to view, modify, add, and delete local users in the graphical user interface.

3.2.1. Using the Users Settings Tool

Press the Super key to enter the Activities Overview, type Users and then press Enter. The Users settings tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Space bar. Alternatively, you can open the Users utility from the Settings menu after clicking your user name in the top right corner of the screen.
To make changes to the user accounts, first select the Unlock button and authenticate yourself as indicated by the dialog box that appears. Note that unless you have superuser privileges, the application will prompt you to authenticate as root. To add and remove users, select the + and - button respectively. To add a user to the administrative group wheel, change the Account Type from Standard to Administrator. To edit a user’s language setting, select the language and a drop-down menu appears.

![Image of the Users Settings Tool]

**Figure 3.1. The Users Settings Tool**

When a new user is created, the account is disabled until a password is set. The Password drop-down menu, shown in Figure 3.2, “The Password Menu”, contains the options to set a password by the administrator immediately, choose a password by the user at the first login, or create a guest account with no password required to log in. You can also disable or enable an account from this menu.
3.3. USING COMMAND-LINE TOOLS

Apart from the Users settings tool described in Section 3.2, “Managing Users in a Graphical Environment”, which is designed for basic managing of users, you can use command line tools for managing users and groups that are listed in Table 3.1, “Command line utilities for managing users and groups”.

Table 3.1. Command line utilities for managing users and groups

<table>
<thead>
<tr>
<th>Utilities</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Displays user and group IDs.</td>
</tr>
<tr>
<td>useradd, usermod, userdel</td>
<td>Standard utilities for adding, modifying, and deleting user accounts.</td>
</tr>
<tr>
<td>groupadd, groupmod, groupdel</td>
<td>Standard utilities for adding, modifying, and deleting groups.</td>
</tr>
<tr>
<td>gpasswd</td>
<td>Utility primarily used for modification of group password in the /etc/gshadow file which is used by the newgrp command.</td>
</tr>
<tr>
<td>pwck, grpck</td>
<td>Utilities that can be used for verification of the password, group, and associated shadow files.</td>
</tr>
</tbody>
</table>
3.3.1. Adding a New User

To add a new user to the system, type the following at a shell prompt as `root`:

```bash
useradd [options] username
```

...where `options` are command-line options as described in Table 3.2, “Common useradd command-line options”.

By default, the `useradd` command creates a locked user account. To unlock the account, run the following command as `root` to assign a password:

```bash
passwd username
```

Optionally, you can set a password aging policy. See the Password Security section in the Red Hat Enterprise Linux 7 Security Guide.

### Table 3.2. Common useradd command-line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-c 'comment'</code></td>
<td><code>comment</code> can be replaced with any string. This option is generally used to specify the full name of a user.</td>
</tr>
<tr>
<td><code>-d home_directory</code></td>
<td>Home directory to be used instead of default <code>/home/username/</code>.</td>
</tr>
<tr>
<td><code>-e date</code></td>
<td>Date for the account to be disabled in the format YYYY-MM-DD.</td>
</tr>
<tr>
<td><code>-f days</code></td>
<td>Number of days after the password expires until the account is disabled. If 0 is specified, the account is disabled immediately after the password expires. If -1 is specified, the account is not disabled after the password expires.</td>
</tr>
<tr>
<td><code>-g group_name</code></td>
<td>Group name or group number for the user’s default (primary) group. The group must exist prior to being specified here.</td>
</tr>
<tr>
<td><code>-G group_list</code></td>
<td>List of additional (supplementary, other than default) group names or group numbers, separated by commas, of which the user is a member. The groups must exist prior to being specified here.</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Create the home directory if it does not exist.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>-M</td>
<td>Do not create the home directory.</td>
</tr>
<tr>
<td>-N</td>
<td>Do not create a user private group for the user.</td>
</tr>
<tr>
<td>-p password</td>
<td>The password encrypted with crypt.</td>
</tr>
<tr>
<td>-r</td>
<td>Create a system account with a UID less than 1000 and without a home directory.</td>
</tr>
<tr>
<td>-s</td>
<td>User's login shell, which defaults to /bin/bash.</td>
</tr>
<tr>
<td>-u uid</td>
<td>User ID for the user, which must be unique and greater than 999.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The default range of IDs for system and normal users has been changed in Red Hat Enterprise Linux 7 from earlier releases. Previously, UID 1-499 was used for system users and values above for normal users. The default range for system users is now 1-999. This change might cause problems when migrating to Red Hat Enterprise Linux 7 with existing users having UIDs and GIDs between 500 and 999. The default ranges of UID and GID can be changed in the `/etc/login.defs` file.

**Explaining the Process**

The following steps illustrate what happens if the command `useradd juan` is issued on a system that has shadow passwords enabled:

1. A new line for `juan` is created in `/etc/passwd`:

```
juan:x:1001:1001::/home/juan:/bin/bash
```

The line has the following characteristics:

- It begins with the user name `juan`.
- There is an `x` for the password field indicating that the system is using shadow passwords.
- A UID greater than 999 is created. Under Red Hat Enterprise Linux 7, UIDs below 1000 are reserved for system use and should not be assigned to users.
- A GID greater than 999 is created. Under Red Hat Enterprise Linux 7, GIDs below 1000 are reserved for system use and should not be assigned to users.
- The optional GECOS information is left blank. The GECOS field can be used to provide additional information about the user, such as their full name or phone number.
- The home directory for `juan` is set to `/home/juan/`.
- The default shell is set to `/bin/bash`. 
2. A new line for `juan` is created in `/etc/shadow`:

```
juan:!!:14798:0:99999:7:::
```

The line has the following characteristics:

- It begins with the user name `juan`.
- Two exclamation marks (`!!`) appear in the password field of the `/etc/shadow` file, which locks the account.

**NOTE**

If an encrypted password is passed using the `-p` flag, it is placed in the `/etc/shadow` file on the new line for the user.

- The password is set to never expire.

3. A new line for a group named `juan` is created in `/etc/group`:

```
juan:x:1001:
```

A group with the same name as a user is called a *user private group*. For more information on user private groups, see Section 3.1.1, “User Private Groups”.

The line created in `/etc/group` has the following characteristics:

- It begins with the group name `juan`.
- An `x` appears in the password field indicating that the system is using shadow group passwords.
- The GID matches the one listed for `juan`'s primary group in `/etc/passwd`.

4. A new line for a group named `juan` is created in `/etc/gshadow`:

```
juan:!:::
```

The line has the following characteristics:

- It begins with the group name `juan`.
- An exclamation mark (`!`) appears in the password field of the `/etc/gshadow` file, which locks the group.
- All other fields are blank.

5. A directory for user `juan` is created in the `/home` directory:

```
~]$ ls -ld /home/juan
drwx------. 4 juan juan 4096 Mar 3 18:23 /home/juan
```
This directory is owned by user juan and group juan. It has read, write, and execute privileges only for the user juan. All other permissions are denied.

6. The files within the /etc/skel/ directory (which contain default user settings) are copied into the new /home/juan/ directory:

```
~]# ls -la /home/juan
total 28
drwx-------. 4 juan juan 4096 Mar  3 18:23 .
drwxr-xr-x. 5 root root 4096 Mar  3 18:23 ..
-rw-r--r--. 1 juan juan 18 Jun 22 2010 .bash_logout
-rw-r--r--. 1 juan juan 176 Jun 22 2010 .bash_profile
-rw-r--r--. 1 juan juan 124 Jun 22 2010 .bashrc
drwxr-xr-x. 4 juan juan 4096 Nov 23 15:09 .mozilla
```

At this point, a locked account called juan exists on the system. To activate it, the administrator must next assign a password to the account using the passwd command and, optionally, set password aging guidelines (see the Password Security section in the Red Hat Enterprise Linux 7 Security Guide for details).

### 3.3.2. Adding a New Group

To add a new group to the system, type the following at a shell prompt as root:

```
$ groupadd [options] group_name
```

…where options are command-line options as described in Table 3.3, “Common groupadd command-line options”.

#### Table 3.3. Common groupadd command-line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>When used with -g gid and gid already exists, groupadd will choose another unique gid for the group.</td>
</tr>
<tr>
<td>-g gid</td>
<td>Group ID for the group, which must be unique and greater than 999.</td>
</tr>
<tr>
<td>-K, --key key=value</td>
<td>Override /etc/login.defs defaults.</td>
</tr>
<tr>
<td>-o, --non-unique</td>
<td>Allows creating groups with duplicate GID.</td>
</tr>
<tr>
<td>-p, --password password</td>
<td>Use this encrypted password for the new group.</td>
</tr>
<tr>
<td>-r</td>
<td>Create a system group with a GID less than 1000.</td>
</tr>
</tbody>
</table>

### 3.3.3. Adding an Existing User to an Existing Group

Use the usermod utility to add an already existing user to an already existing group.
Various options of usermod have different impact on user's primary group and on his or her supplementary groups.

To override user's primary group, run the following command as root:

```
~
-]# usermod -g group_name user_name
```

To override user's supplementary groups, run the following command as root:

```
~
-]# usermod -G group_name1,group_name2,... user_name
```

Note that in this case all previous supplementary groups of the user are replaced by the new group or several new groups.

To add one or more groups to user's supplementary groups, run one of the following commands as root:

```
~
-]# usermod -aG group_name1,group_name2,... user_name
```

```
~
-]# usermod --append -G group_name1,group_name2,... user_name
```

Note that in this case the new group is added to user's current supplementary groups.

### 3.3.4. Creating Group Directories

System administrators usually like to create a group for each major project and assign people to the group when they need to access that project's files. With this traditional scheme, file management is difficult; when someone creates a file, it is associated with the primary group to which they belong. When a single person works on multiple projects, it becomes difficult to associate the right files with the right group. However, with the UPG scheme, groups are automatically assigned to files created within a directory with the setgid bit set. The setgid bit makes managing group projects that share a common directory very simple because any files a user creates within the directory are owned by the group that owns the directory.

For example, a group of people need to work on files in the `/opt/myproject/` directory. Some people are trusted to modify the contents of this directory, but not everyone.

1. As root, create the `/opt/myproject/` directory by typing the following at a shell prompt:

   ```
   mkdir /opt/myproject
   ```

2. Add the `myproject` group to the system:

   ```
   groupadd myproject
   ```

3. Associate the contents of the `/opt/myproject/` directory with the `myproject` group:

   ```
   chown root:myproject /opt/myproject
   ```

4. Allow users in the group to create files within the directory and set the setgid bit:

   ```
   chmod 2775 /opt/myproject
   ```
At this point, all members of the myproject group can create and edit files in the /opt/myproject/ directory without the administrator having to change file permissions every time users write new files. To verify that the permissions have been set correctly, run the following command:

```
~]# ls -ld /opt/myproject
drwxrwsr-x. 3 root myproject 4096 Mar  3 18:31 /opt/myproject
```

5. Add users to the myproject group:

```
usermod -aG myproject username
```

### 3.3.5. Setting Default Permissions for New Files Using umask

When a process creates a file, the file has certain default permissions, for example, `-rw-rw-r--`. These initial permissions are partially defined by the file mode creation mask also called file permission mask or umask. Every process has its own umask, for example, `bash` has `umask 0022` by default. Process `umask` can be changed.

**What umask consists of**

A `umask` consists of bits corresponding to standard file permissions. For example, for `umask 0137`, the digits mean that:

- **0** = no meaning, it is always 0 (umask does not affect special bits)
- **1** = for owner permissions, the execute bit is set
- **3** = for group permissions, the execute and write bits are set
- **7** = for others permissions, the execute, write, and read bits are set

**Umasks** can be represented in binary, octal, or symbolic notation. For example, the octal representation `0137` equals symbolic representation `u=rw-, g=r--, o=---`. Symbolic notation specification is the reverse of the octal notation specification: it shows the allowed permissions, not the prohibited permissions.

**How umask works**

*Umask prohibits permissions* from being set for a file:

- When a bit is set in `umask`, it is unset in the file.
- When a bit is not set in `umask`, it can be set in the file, depending on other factors.

The following figure shows how `umask 0137` affects creating a new file.
IMPORTANT

For security reasons, a regular file cannot have execute permissions by default. Therefore, even if umask is 0000, which does not prohibit any permissions, a new regular file still does not have execute permissions. However, directories can be created with execute permissions:

```
[john@server tmp]$ umask 0000
[john@server tmp]$ touch file
[john@server tmp]$ mkdir directory
[john@server tmp]$ ls -lh .
total 0  
  drwxrwxrwx. 2 john john 40 Nov 2 13:17 directory
  -rw-rw-rw-. 1 john john  0 Nov 2 13:17 file
```

3.3.5.1. Managing umask in Shells

For popular shells, such as bash, ksh, zsh and tcsh, umask is managed using the umask shell builtin. Processes started from shell inherit its umask.

Displaying the current mask

To show the current umask in octal notation:

```
-]$ umask
0022
```

To show the current umask in symbolic notation:

```
-]$ umask -S
u=rwx,g=rx,o=rx
```
Setting mask in shell using `umask`
To set `umask` for the current shell session using octal notation run:

```
~]$ umask octal_mask
```

Substitute `octal_mask` with four or less digits from 0 to 7. When three or less digits are provided, permissions are set as if the command contained leading zeros. For example, `umask 7` translates to `0007`.

**Example 3.1. Setting umask Using Octal Notation**

To prohibit new files from having write and execute permissions for owner and group, and from having any permissions for others:

```
~]$ umask 0337
```

Or simply:

```
~]$ umask 337
```

To set `umask` for the current shell session using symbolic notation:

```
~]$ umask -S symbolic_mask
```

**Example 3.2. Setting umask Using Symbolic Notation**

To set `umask 0337` using symbolic notation:

```
~]$ umask -S u=r,g=r,o=
```

Working with the default shell `umask`
Shells usually have a configuration file where their default `umask` is set. For `bash`, it is `/etc/bashrc`. To show the default `bash` umask:

```
~]$ grep -i -B 1 umask /etc/bashrc
```

The output shows if `umask` is set, either using the `umask` command or the `UMASK` variable. In the following example, `umask` is set to `022` using the `umask` command:

```
~]$ grep -i -B 1 umask /etc/bashrc
  # By default, we want umask to get set. This sets it for non-login shell.
  --
    if [ $UID -gt 199 ] && [ "$id -gn" = "$id -un" ]; then
      umask 002
    else
      umask 022
  ...
```
To change the default *umask* for *bash*, change the *umask* command call or the *UMASK* variable assignment in `/etc/bashrc`. This example changes the default *umask* to 0227:

```bash
if [ $UID -gt 199 ] && [ "$id -gn" = "$id -un" ]; then
    umask 002
else
    umask 227

Working with the default shell *umask* of a specific user

By default, *bash* *umask* of a new user defaults to the one defined in `/etc/bashrc`.

To change *bash* *umask* for a particular user, add a call to the *umask* command in `$HOME/.bashrc` file of that user. For example, to change *bash* *umask* of user *john* to 0227:

```
john@server ~]$ echo 'umask 227' >> /home/john/.bashrc
```

Setting default permissions for newly created home directories

To change permissions with which user home directories are created, change the *UMASK* variable in the `/etc/login.defs` file:

```
# The permission mask is initialized to this value. If not specified,
# the permission mask will be initialized to 022.
UMASK 077
```

3.4. ADDITIONAL RESOURCES

For more information on how to manage users and groups on Red Hat Enterprise Linux, see the resources listed below.

**Installed Documentation**

For information about various utilities for managing users and groups, see the following manual pages:

- **useradd(8)** – The manual page for the *useradd* command documents how to use it to create new users.
- **userdel(8)** – The manual page for the *userdel* command documents how to use it to delete users.
- **usermod(8)** – The manual page for the *usermod* command documents how to use it to modify users.
- **groupadd(8)** – The manual page for the *groupadd* command documents how to use it to create new groups.
- **groupdel(8)** – The manual page for the *groupdel* command documents how to use it to delete groups.
- **groupmod(8)** – The manual page for the *groupmod* command documents how to use it to modify group membership.
- **gpasswd(1)** – The manual page for the *gpasswd* command documents how to manage the `/etc/group` file.
- **grpck(8)** – The manual page for the *grpck* command documents how to use it to verify the
integrity of the /etc/group file.

- pwck(8) — The manual page for the pwck command documents how to use it to verify the integrity of the /etc/passwd and /etc/shadow files.

- pwconv(8) — The manual page for the pwconv, pwunconv, grpconv, and grpunconv commands documents how to convert shadowed information for passwords and groups.

- id(1) — The manual page for the id command documents how to display user and group IDs.

- umask(2) — The manual page for the umask command documents how to work with the file mode creation mask.

For information about related configuration files, see:

- group(5) — The manual page for the /etc/group file documents how to use this file to define system groups.

- passwd(5) — The manual page for the /etc/passwd file documents how to use this file to define user information.

- shadow(5) — The manual page for the /etc/shadow file documents how to use this file to set passwords and account expiration information for the system.

Online Documentation

- Red Hat Enterprise Linux 7 Security Guide — The Security Guide for Red Hat Enterprise Linux 7 provides additional information how to ensure password security and secure the workstation by enabling password aging and user account locking.

- Chapter 5, Gaining Privileges documents how to gain administrative privileges by using the su and sudo commands.
CHAPTER 4. ACCESS CONTROL LISTS

Files and directories have permission sets for the owner of the file, the group associated with the file, and all other users for the system. However, these permission sets have limitations. For example, different permissions cannot be configured for different users. Thus, Access Control Lists (ACLs) were implemented.

The Red Hat Enterprise Linux kernel provides ACL support for the ext3 file system and NFS-exported file systems. ACLs are also recognized on ext3 file systems accessed via Samba.

Along with support in the kernel, the acl package is required to implement ACLs. It contains the utilities used to add, modify, remove, and retrieve ACL information.

The cp and mv commands copy or move any ACLs associated with files and directories.

4.1. MOUNTING FILE SYSTEMS

Before using ACLs for a file or directory, the partition for the file or directory must be mounted with ACL support. If it is a local ext3 file system, it can mounted with the following command:

```
mount -t ext3 -o acl device-name partition
```

For example:

```
mount -t ext3 -o acl /dev/VolGroup00/LogVol02 /work
```

Alternatively, if the partition is listed in the /etc/fstab file, the entry for the partition can include the acl option:

```
LABEL=/work      /work       ext3    acl        1 2
```

If an ext3 file system is accessed via Samba and ACLs have been enabled for it, the ACLs are recognized because Samba has been compiled with the --with-acl-support option. No special flags are required when accessing or mounting a Samba share.

4.1.1. NFS

By default, if the file system being exported by an NFS server supports ACLs and the NFS client can read ACLs, ACLs are utilized by the client system.

To disable ACLs on NFS shares when configuring the server, include the no_acl option in the /etc/exports file. To disable ACLs on an NFS share when mounting it on a client, mount it with the no_acl option via the command line or the /etc/fstab file.

4.2. SETTING ACCESS ACLS

There are two types of ACLs: access ACLs and default ACLs. An access ACL is the access control list for a specific file or directory. A default ACL can only be associated with a directory; if a file within the directory does not have an access ACL, it uses the rules of the default ACL for the directory. Default ACLs are optional.

ACLs can be configured:

1. Per user
2. Per group

3. Via the effective rights mask

4. For users not in the user group for the file

The `setfacl` utility sets ACLs for files and directories. Use the `-m` option to add or modify the ACL of a file or directory:

```
# setfacl -m rules files
```

Rules (rules) must be specified in the following formats. Multiple rules can be specified in the same command if they are separated by commas.

#### u:uid:perms

Sets the access ACL for a user. The user name or UID may be specified. The user may be any valid user on the system.

#### g:gid:perms

Sets the access ACL for a group. The group name or GID may be specified. The group may be any valid group on the system.

#### m:perms

Sets the effective rights mask. The mask is the union of all permissions of the owning group and all of the user and group entries.

#### o:perms

Sets the access ACL for users other than the ones in the group for the file.

Permissions (perms) must be a combination of the characters `r`, `w`, and `x` for read, write, and execute.

If a file or directory already has an ACL, and the `setfacl` command is used, the additional rules are added to the existing ACL or the existing rule is modified.

**Example 4.1. Give read and write permissions**

For example, to give read and write permissions to user andrius:

```
# setfacl -m u:andrius:rw /project/somefile
```

To remove all the permissions for a user, group, or others, use the `-x` option and do not specify any permissions:

```
# setfacl -x rules files
```

**Example 4.2. Remove all permissions**

For example, to remove all permissions from the user with UID 500:

```
# setfacl -x u:500 /project/somefile
```
4.3. SETTING DEFAULT ACLS

To set a default ACL, add \texttt{d:} before the rule and specify a directory instead of a file name.

\textbf{Example 4.3. Setting default ACLs}

For example, to set the default ACL for the \texttt{/share/} directory to read and execute for users not in the user group (an access ACL for an individual file can override it):

\begin{verbatim}
# setfacl -m d:o:rx /share
\end{verbatim}

4.4. RETRIEVING ACLS

To determine the existing ACLs for a file or directory, use the \texttt{getfacl} command. In the example below, the \texttt{getfacl} is used to determine the existing ACLs for a file.

\textbf{Example 4.4. Retrieving ACLs}

\begin{verbatim}
# getfacl home/john/picture.png
\end{verbatim}

The above command returns the following output:

\begin{verbatim}
# file: home/john/picture.png
# owner: john
# group: john
user::rw-
group::r--
other::r--
\end{verbatim}

If a directory with a default ACL is specified, the default ACL is also displayed as illustrated below. For example, \texttt{getfacl home/sales/} will display similar output:

\begin{verbatim}
# file: home/sales/
# owner: john
# group: john
user::rw-
user:barryg:r--
group::r--
mask::r--
other::r--
default:user::rwx
default:user:john:rwx
default:group::r-x
default:mask::rwx
default:other::r-x
\end{verbatim}
4.5. ARCHIVING FILE SYSTEMS WITH ACLS

By default, the `dump` command now preserves ACLs during a backup operation. When archiving a file or file system with `tar`, use the `--acls` option to preserve ACLs. Similarly, when using `cp` to copy files with ACLs, include the `--preserve=mode` option to ensure that ACLs are copied across too. In addition, the `-a` option (equivalent to `-dR --preserve=all`) of `cp` also preserves ACLs during a backup along with other information such as timestamps, SELinux contexts, and the like. For more information about `dump`, `tar`, or `cp`, refer to their respective `man` pages.

The `star` utility is similar to the `tar` utility in that it can be used to generate archives of files; however, some of its options are different. Refer to Table 4.1, “Command Line Options for star” for a listing of more commonly used options. For all available options, refer to `man star`. The `star` package is required to use this utility.

Table 4.1. Command Line Options for star

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-c</code></td>
<td>Creates an archive file.</td>
</tr>
<tr>
<td><code>-n</code></td>
<td>Do not extract the files; use in conjunction with <code>-X</code> to show what extracting the files does.</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Replaces files in the archive. The files are written to the end of the archive file, replacing any files with the same path and file name.</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Displays the contents of the archive file.</td>
</tr>
<tr>
<td><code>-u</code></td>
<td>Updates the archive file. The files are written to the end of the archive if they do not exist in the archive, or if the files are newer than the files of the same name in the archive. This option only works if the archive is a file or an unblocked tape that may backspace.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>Extracts the files from the archive. If used with <code>-U</code> and a file in the archive is older than the corresponding file on the file system, the file is not extracted.</td>
</tr>
<tr>
<td><code>-help</code></td>
<td>Displays the most important options.</td>
</tr>
<tr>
<td><code>-xhelp</code></td>
<td>Displays the least important options.</td>
</tr>
<tr>
<td><code>-/</code></td>
<td>Do not strip leading slashes from file names when extracting the files from an archive. By default, they are stripped when files are extracted.</td>
</tr>
<tr>
<td><code>-acl</code></td>
<td>When creating or extracting, archives or restores any ACLs associated with the files and directories.</td>
</tr>
</tbody>
</table>
4.6. COMPATIBILITY WITH OLDER SYSTEMS

If an ACL has been set on any file on a given file system, that file system has the `ext_attr` attribute. This attribute can be seen using the following command:

```
# tune2fs -l filesystem-device
```

A file system that has acquired the `ext_attr` attribute can be mounted with older kernels, but those kernels do not enforce any ACLs which have been set.

Versions of the `e2fsck` utility included in version 1.22 and higher of the `e2fsprogs` package (including the versions in Red Hat Enterprise Linux 2.1 and 4) can check a file system with the `ext_attr` attribute. Older versions refuse to check it.

4.7. ACL REFERENCES

Refer to the following man pages for more information.

- `man acl` – Description of ACLs
- `man getfacl` – Discusses how to get file access control lists
- `man setfacl` – Explains how to set file access control lists
- `man star` – Explains more about the `star` utility and its many options
CHAPTER 5. GAINING PRIVILEGES

System administrators, and in some cases users, need to perform certain tasks with administrative access. Accessing the system as the root user is potentially dangerous and can lead to widespread damage to the system and data. This chapter covers ways to gain administrative privileges using the setuid programs such as su and sudo. These programs allow specific users to perform tasks which would normally be available only to the root user while maintaining a higher level of control and system security.

See the Red Hat Enterprise Linux 7 Security Guide for more information on administrative controls, potential dangers and ways to prevent data loss resulting from improper use of privileged access.

5.1. CONFIGURING ADMINISTRATIVE ACCESS USING THE SU UTILITY

When a user executes the su command, they are prompted for the root password and, after authentication, are given a root shell prompt.

Once logged in using the su command, the user is the root user and has absolute administrative access to the system. Note that this access is still subject to the restrictions imposed by SELinux, if it is enabled. In addition, once a user has become root, it is possible for them to use the su command to change to any other user on the system without being prompted for a password.

Because this program is so powerful, administrators within an organization may want to limit who has access to the command.

One of the simplest ways to do this is to add users to the special administrative group called wheel. To do this, type the following command as root:

```
~# usermod -a -G wheel username
```

In the previous command, replace username with the user name you want to add to the wheel group.

You can also use the Users settings tool to modify group memberships, as follows. Note that you need administrator privileges to perform this procedure.

1. Press the Super key to enter the Activities Overview, type Users and then press Enter. The Users settings tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Spacebar.
2. To enable making changes, click the Unlock button, and enter a valid administrator password.
3. Click a user icon in the left column to display the user’s properties in the right pane.
4. Change the Account Type from Standard to Administrator. This will add the user to the wheel group.

See Section 3.2, “Managing Users in a Graphical Environment” for more information about the Users tool.

After you add the desired users to the wheel group, it is advisable to only allow these specific users to use the su command. To do this, edit the Pluggable Authentication Module (PAM) configuration file for su, /etc/pam.d/su. Open this file in a text editor and uncomment the following line by removing the # character:
This change means that only members of the administrative group `wheel` can switch to another user using the `su` command.

**NOTE**

The root user is part of the wheel group by default.

5.2. CONFIGURING ADMINISTRATIVE ACCESS USING THE SUDO UTILITY

The `sudo` command offers another approach to giving users administrative access. When trusted users precede an administrative command with `sudo`, they are prompted for their own password. Then, when they have been authenticated and assuming that the command is permitted, the administrative command is executed as if they were the root user.

The basic format of the `sudo` command is as follows:

```
sudo command
```

In the above example, `command` would be replaced by a command normally reserved for the root user, such as `mount`.

The `sudo` command allows for a high degree of flexibility. For instance, only users listed in the `/etc/sudoers` configuration file are allowed to use the `sudo` command and the command is executed in the user's shell, not a root shell. This means the root shell can be completely disabled as shown in the Red Hat Enterprise Linux 7 Security Guide.

Each successful authentication using the `sudo` command is logged to the file `/var/log/messages` and the command issued along with the issuer's user name is logged to the file `/var/log/secure`. If additional logging is required, use the `pam_tty_audit` module to enable TTY auditing for specified users by adding the following line to your `/etc/pam.d/system-auth` file:

```
session required pam_tty_audit.so disable=pattern enable=pattern
```

where `pattern` represents a comma-separated listing of users with an optional use of globs. For example, the following configuration will enable TTY auditing for the root user and disable it for all other users:

```
session required pam_tty_audit.so disable=* enable=root
```

**IMPORTANT**

Configuring the `pam_tty_audit` PAM module for TTY auditing records only TTY input. This means that, when the audited user logs in, `pam_tty_audit` records the exact keystrokes the user makes into the `/var/log/audit/audit.log` file. For more information, see the `pam_tty_audit(8)` manual page.
Another advantage of the `sudo` command is that an administrator can allow different users access to specific commands based on their needs.

Administrators wanting to edit the `sudo` configuration file, `/etc/sudoers`, should use the `visudo` command.

To give someone full administrative privileges, type `visudo` and add a line similar to the following in the user privilege specification section:

```
juan ALL=(ALL) ALL
```

This example states that the user, `juan`, can use `sudo` from any host and execute any command.

The example below illustrates the granularity possible when configuring `sudo`:

```
%users localhost=/usr/sbin/shutdown -h now
```

This example states that any member of the `users` system group can issue the command `/sbin/shutdown -h now` as long as it is issued from the console.

The man page for `sudoers` has a detailed listing of options for this file.

**IMPORTANT**

There are several potential risks to keep in mind when using the `sudo` command. You can avoid them by editing the `/etc/sudoers` configuration file using `visudo` as described above. Leaving the `/etc/sudoers` file in its default state gives every user in the wheel group unlimited root access.

- By default, `sudo` stores the password for a five minute timeout period. Any subsequent uses of the command during this period will not prompt the user for a password. This could be exploited by an attacker if the user leaves his workstation unattended and unlocked while still being logged in. This behavior can be changed by adding the following line to the `/etc/sudoers` file:

  ```
  Defaults    timestamp_timeout=value
  ```

  where `value` is the desired timeout length in minutes. Setting the `value` to 0 causes `sudo` to require a password every time.

- If an account is compromised, an attacker can use `sudo` to open a new shell with administrative privileges:

  ```
  sudo /bin/bash
  ```

  Opening a new shell as `root` in this or similar fashion gives the attacker administrative access for a theoretically unlimited amount of time, bypassing the timeout period specified in the `/etc/sudoers` file and never requiring the attacker to input a password for `sudo` again until the newly opened session is closed.

5.3. ADDITIONAL RESOURCES
While programs allowing users to gain administrative privileges are a potential security risk, security itself is beyond the scope of this particular book. You should therefore refer to the resources listed below for more information regarding security and privileged access.

**Installed Documentation**

- `su(1)` — The manual page for `su` provides information regarding the options available with this command.

- `sudo(8)` — The manual page for `sudo` includes a detailed description of this command and lists options available for customizing its behavior.

- `pam(8)` — The manual page describing the use of Pluggable Authentication Modules (PAM) for Linux.

**Online Documentation**

- Red Hat Enterprise Linux 7 Security Guide — The Security Guide for Red Hat Enterprise Linux 7 provides a more detailed look at potential security issues pertaining to the `setuid` programs as well as techniques used to alleviate these risks.

**See Also**

- Chapter 3, Managing Users and Groups documents how to manage system users and groups in the graphical user interface and on the command line.
PART II. SUBSCRIPTION AND SUPPORT

To receive updates to the software on a Red Hat Enterprise Linux system it must be subscribed to the Red Hat Content Delivery Network (CDN) and the appropriate repositories enabled. This part describes how to subscribe a system to the Red Hat Content Delivery Network.

Red Hat provides support via the Customer Portal, and you can access this support directly from the command line using the Red Hat Support Tool. This part describes the use of this command-line tool.
CHAPTER 6. REGISTERING THE SYSTEM AND MANAGING SUBSCRIPTIONS

The subscription service provides a mechanism to handle Red Hat software inventory and allows you to install additional software or update already installed programs to newer versions using the **yum** package manager. In Red Hat Enterprise Linux 7 the recommended way to register your system and attach subscriptions is to use *Red Hat Subscription Management*.

**NOTE**

It is also possible to register the system and attach subscriptions after installation during the initial setup process. For detailed information about the initial setup see the Initial Setup chapter in the *Installation Guide* for Red Hat Enterprise Linux 7. Note that the Initial Setup application is only available on systems installed with the X Window System at the time of installation.

6.1. REGISTERING THE SYSTEM AND ATTACHING SUBSCRIPTIONS

Complete the following steps to register your system and attach one or more subscriptions using *Red Hat Subscription Management*. Note that all *subscription-manager* commands are supposed to be run as *root*.

1. Run the following command to register your system. You will be prompted to enter your user name and password. Note that the user name and password are the same as your login credentials for Red Hat Customer Portal.

```
subscription-manager register
```

2. Determine the pool ID of a subscription that you require. To do so, type the following at a shell prompt to display a list of all subscriptions that are available for your system:

```
subscription-manager list --available
```

For each available subscription, this command displays its name, unique identifier, expiration date, and other details related to your subscription. To list subscriptions for all architectures, add the `--all` option. The pool ID is listed on a line beginning with **Pool ID**.

3. Attach the appropriate subscription to your system by entering a command as follows:

```
subscription-manager attach --pool=pool_id
```

Replace **pool_id** with the pool ID you determined in the previous step.

To verify the list of subscriptions your system has currently attached, at any time, run:

```
subscription-manager list --consumed
```

For more details on how to register your system using Red Hat Subscription Management and associate it with subscriptions, see the designated solution article. For comprehensive information about subscriptions, see the *Red Hat Subscription Management* collection of guides.
6.2. MANAGING SOFTWARE REPOSITORIES

When a system is subscribed to the Red Hat Content Delivery Network, a repository file is created in the /etc/yum.repos.d/ directory. To verify that, use yum to list all enabled repositories:

```
yum repolist
```

Red Hat Subscription Management also allows you to manually enable or disable software repositories provided by Red Hat. To list all available repositories, use the following command:

```
subscription-manager repos --list
```

The repository names depend on the specific version of Red Hat Enterprise Linux you are using and are in the following format:

```
rhel-version-variant-rpms
rhel-version-variant-debug-rpms
rhel-version-variant-source-rpms
```

Where version is the Red Hat Enterprise Linux system version (6 or 7), and variant is the Red Hat Enterprise Linux system variant (server or workstation), for example:

```
rhel-7-server-rpms
rhel-7-server-debug-rpms
rhel-7-server-source-rpms
```

To enable a repository, enter a command as follows:

```
subscription-manager repos --enable repository
```

Replace repository with the name of the repository to enable.

Similarly, to disable a repository, use the following command:

```
subscription-manager repos --disable repository
```

Section 8.5, “Configuring Yum and Yum Repositories” provides detailed information about managing software repositories using yum.

6.3. REMOVING SUBSCRIPTIONS

To remove a particular subscription, complete the following steps.

1. Determine the serial number of the subscription you want to remove by listing information about already attached subscriptions:

```
subscription-manager list --consumed
```

The serial number is the number listed as serial. For instance, 744993814251016831 in the example below:

```
SKU:               ES0113909
```
Contract:          01234567  
Account:           1234567  
Serial:            744993814251016831  
Pool ID:           8a85f9894bba16dc014bccdd905a5e23  
Active:            False  
Quantity Used:     1  
Service Level:     SELF-SUPPORT  
Service Type:      L1-L3  
Status Details:    
Subscription Type: Standard  
Starts:            02/27/2015  
Ends:              02/27/2016  
System Type:       Virtual  

2. Enter a command as follows to remove the selected subscription:

```
subscription-manager remove --serial=serial_number
```

Replace `serial_number` with the serial number you determined in the previous step.

To remove all subscriptions attached to the system, run the following command:

```
subscription-manager remove --all
```

6.4. ADDITIONAL RESOURCES

For more information on how to register your system using Red Hat Subscription Management and associate it with subscriptions, see the resources listed below.

Installed Documentation

- `subscription-manager(8)` – the manual page for Red Hat Subscription Management provides a complete list of supported options and commands.

Related Books

- **Red Hat Subscription Management** collection of guides – These guides contain detailed information how to use Red Hat Subscription Management.

- **Installation Guide** – see the Initial Setup chapter for detailed information on how to register during the initial setup process.

See Also

- **Chapter 5, Gaining Privileges** documents how to gain administrative privileges by using the `su` and `sudo` commands.

- **Chapter 8, Yum** provides information about using the `yum` packages manager to install and update software.
CHAPTER 7. ACCESSING SUPPORT USING THE RED HAT
SUPPORT TOOL

The Red Hat Support Tool, in the redhat-support-tool package, can function as both an interactive
shell and as a single-execution program. It can be run over SSH or from any terminal. It enables, for
example, searching the Red Hat Knowledgebase from the command line, copying solutions directly on
the command line, opening and updating support cases, and sending files to Red Hat for analysis.

7.1. INSTALLING THE RED HAT SUPPORT TOOL

The Red Hat Support Tool is installed by default on Red Hat Enterprise Linux. If required, to ensure
that it is, enter the following command as root:

```
~# yum install redhat-support-tool
```

7.2. REGISTERING THE RED HAT SUPPORT TOOL USING THE
COMMAND LINE

To register the Red Hat Support Tool to the customer portal using the command line, proceed as
follows:

1. `~# redhat-support-tool config user username`
   Where `username` is the user name of the Red Hat Customer Portal account.

2. `~# redhat-support-tool config password`
   Please enter the password for `username`:

7.3. USING THE RED HAT SUPPORT TOOL IN INTERACTIVE SHELL
MODE

To start the tool in interactive mode, enter the following command:

```
~$ redhat-support-tool
Welcome to the Red Hat Support Tool. Command (? for help):
```

The tool can be run as an unprivileged user, with a consequently reduced set of commands, or as root.

The commands can be listed by entering the `?` character. The program or menu selection can be exited
by entering the `q` or `e` character. You will be prompted for your Red Hat Customer Portal user name
and password when you first search the Knowledgebase or support cases. Alternately, set the user
name and password for your Red Hat Customer Portal account using interactive mode, and optionally
save it to the configuration file.

7.4. CONFIGURING THE RED HAT SUPPORT TOOL

When in interactive mode, the configuration options can be listed by entering the command `config
- -help:`
Welcome to the Red Hat Support Tool.
Command (? for help): config --help

Usage: config [options] config.option <new option value>

Use the 'config' command to set or get configuration file values.
Options:
- h, --help    show this help message and exit
- g, --global  Save configuration option in /etc/redhat-support-tool.conf.
- u, --unset   Unset configuration option.

The configuration file options which can be set are:
  user      : The Red Hat Customer Portal user.
  debug     : CRITICAL, ERROR, WARNING, INFO, or DEBUG
  url       : The support services URL.
  Default=https://api.access.redhat.com
  proxy_url : A proxy server URL.
  proxy_user: A proxy server user.
  proxy_password: A password for the proxy server user.
  ssl_ca    : Path to certificate authorities to trust during communication.
  kern_debug_dir: Path to the directory where kernel debug symbols should be downloaded and cached. Default=/var/lib/redhat-support-tool/debugkernels

Examples:
- config user
- config user my-rhn-username
- config --unset user

Procedure 7.1. Registering the Red Hat Support Tool Using Interactive Mode

To register the Red Hat Support Tool to the customer portal using interactive mode, proceed as follows:

1. Start the tool by entering the following command:

   ~]# redhat-support-tool

2. Enter your Red Hat Customer Portal user name:

   Command (? for help): config user username

   To save your user name to the global configuration file, add the -g option.

3. Enter your Red Hat Customer Portal password:

   Command (? for help): config password
   Please enter the password for username:

7.4.1. Saving Settings to the Configuration Files
The Red Hat Support Tool, unless otherwise directed, stores values and options locally in the home directory of the current user, using the ~/.redhat-support-tool/redhat-support-tool.conf configuration file. If required, it is recommended to save passwords to this file because it is only readable by that particular user. When the tool starts, it will read values from the global configuration file /etc/redhat-support-tool.conf and from the local configuration file. Locally stored values and options take precedence over globally stored settings.

**WARNING**

It is recommended not to save passwords in the global /etc/redhat-support-tool.conf configuration file because the password is just base64 encoded and can easily be decoded. In addition, the file is world readable.

To save a value or option to the global configuration file, add the -g, --global option as follows:

```
Command (? for help): config setting -g value
```

**NOTE**

In order to be able to save settings globally, using the -g, --global option, the Red Hat Support Tool must be run as root because normal users do not have the permissions required to write to /etc/redhat-support-tool.conf.

To remove a value or option from the local configuration file, add the -u, --unset option as follows:

```
Command (? for help): config setting -u value
```

This will clear, unset, the parameter from the tool and fall back to the equivalent setting in the global configuration file, if available.

**NOTE**

When running as an unprivileged user, values stored in the global configuration file cannot be removed using the -u, --unset option, but they can be cleared, unset, from the current running instance of the tool by using the -g, --global option simultaneously with the -u, --unset option. If running as root, values and options can be removed from the global configuration file using -g, --global simultaneously with the -u, --unset option.

### 7.5. OPENING AND UPDATING SUPPORT CASES USING INTERACTIVE MODE

**Procedure 7.2. Opening a New Support Case Using Interactive Mode**

To open a new support case using interactive mode, proceed as follows:
1. Start the tool by entering the following command:

   ```shell
   ~]# redhat-support-tool
   ```

2. Enter the `opencase` command:

   ```shell
   Command (?) for help): opencase
   ```

3. Follow the on screen prompts to select a product and then a version.

4. Enter a summary of the case.

5. Enter a description of the case and press `Ctrl+D` on an empty line when complete.

6. Select a severity of the case.

7. Optionally chose to see if there is a solution to this problem before opening a support case.

8. Confirm you would still like to open the support case.

   ```shell
   Support case 0123456789 has successfully been opened
   ```

9. Optionally chose to attach an SOS report.

10. Optionally chose to attach a file.

### Procedure 7.3. Viewing and Updating an Existing Support Case Using Interactive Mode

To view and update an existing support case using interactive mode, proceed as follows:

1. Start the tool by entering the following command:

   ```shell
   ~]# redhat-support-tool
   ```

2. Enter the `getcase` command:

   ```shell
   Command (?) for help): getcase case-number
   ```

   Where `case-number` is the number of the case you want to view and update.

3. Follow the on screen prompts to view the case, modify or add comments, and get or add attachments.

### Procedure 7.4. Modifying an Existing Support Case Using Interactive Mode

To modify the attributes of an existing support case using interactive mode, proceed as follows:

1. Start the tool by entering the following command:

   ```shell
   ~]# redhat-support-tool
   ```

2. Enter the `modifycase` command:

   ```shell
   Command (?) for help): modifycase case-number
   ```
Where case-number is the number of the case you want to view and update.

3. The modify selection list appears:

   Type the number of the attribute to modify or 'e' to return to the previous menu.
   1 Modify Type
   2 Modify Severity
   3 Modify Status
   4 Modify Alternative-ID
   5 Modify Product
   6 Modify Version
   End of options.

   Follow the on screen prompts to modify one or more of the options.

4. For example, to modify the status, enter 3:

   Selection: 3
   1   Waiting on Customer
   2   Waiting on Red Hat
   3   Closed
   Please select a status (or 'q' to exit):

7.6. VIEWING SUPPORT CASES ON THE COMMAND LINE

Viewing the contents of a case on the command line provides a quick and easy way to apply solutions from the command line.

To view an existing support case on the command line, enter a command as follows:

   ~]# redhat-support-tool getcase case-number

Where case-number is the number of the case you want to download.

7.7. ADDITIONAL RESOURCES

The Red Hat Knowledgebase article Red Hat Support Tool has additional information, examples, and video tutorials.
PART III. INSTALLING AND MANAGING SOFTWARE

All software on a Red Hat Enterprise Linux system is divided into RPM packages, which can be installed, upgraded, or removed. This part describes how to manage packages on Red Hat Enterprise Linux using Yum.
CHAPTER 8. YUM

Yum is the Red Hat package manager that is able to query for information about available packages, fetch packages from repositories, install and uninstall them, and update an entire system to the latest available version. Yum performs automatic dependency resolution when updating, installing, or removing packages, and thus is able to automatically determine, fetch, and install all available dependent packages.

Yum can be configured with new, additional repositories, or package sources, and also provides many plug-ins which enhance and extend its capabilities. Yum is able to perform many of the same tasks that RPM can; additionally, many of the command-line options are similar. Yum enables easy and simple package management on a single machine or on groups of them.

The following sections assume your system was registered with Red Hat Subscription Management during installation as described in the Red Hat Enterprise Linux 7 Installation Guide. If your system is not subscribed, see Chapter 6, Registering the System and Managing Subscriptions.

IMPORTANT

Yum provides secure package management by enabling GPG (Gnu Privacy Guard; also known as GnuPG) signature verification on GPG-signed packages to be turned on for all package repositories (package sources), or for individual repositories. When signature verification is enabled, yum will refuse to install any packages not GPG-signed with the correct key for that repository. This means that you can trust that the RPM packages you download and install on your system are from a trusted source, such as Red Hat, and were not modified during transfer. See Section 8.5, “Configuring Yum and Yum Repositories” for details on enabling signature-checking with yum, or Section A.3.2, “Checking Package Signatures” for information on working with and verifying GPG-signed RPM packages in general.

Yum also enables you to easily set up your own repositories of RPM packages for download and installation on other machines. When possible, yum uses parallel download of multiple packages and metadata to speed up downloading.

Learning yum is a worthwhile investment because it is often the fastest way to perform system administration tasks, and it provides capabilities beyond those provided by the PackageKit graphical package management tools.

NOTE

You must have superuser privileges in order to use yum to install, update or remove packages on your system. All examples in this chapter assume that you have already obtained superuser privileges by using either the su or sudo command.

8.1. CHECKING FOR AND UPDATING PACKAGES

Yum enables you to check if your system has any updates waiting to be applied. You can list packages that need to be updated and update them as a whole, or you can update a selected individual package.

8.1.1. Checking For Updates

To see which installed packages on your system have updates available, use the following command:
Example 8.1. Example output of the yum check-update command

The output of **yum check-update** can look as follows:

```bash
~ ]# yum check-update
Loaded plugins: product-id, search-disabled-repos, subscription-manager
```
```
dracut.x86_64 033-360.el7_2 rhel-7-server-rpms
```
```
dracut-config-rescue.x86_64 033-360.el7_2 rhel-7-server-rpms
```
```
kernel.x86_64 3.10.0-327.el7 rhel-7-server-rpms
```
```
rpm.x86_64 4.11.3-17.el7 rhel-7-server-rpms
```
```
rpm.libs.x86_64 4.11.3-17.el7 rhel-7-server-rpms
```
```
rpm-python.x86_64 4.11.3-17.el7 rhel-7-server-rpms
```
```
yum.noarch 3.4.3-132.el7 rhel-7-server-rpms
```

The packages in the above output are listed as having updates available. The first package in the list is **dracut**. Each line in the example output consists of several rows, in case of **dracut**:

- **dracut** — the name of the package,
- **x86_64** — the CPU architecture the package was built for,
- **033** — the version of the updated package to be installed,
- **360.el7** — the release of the updated package,
- **_2** — a build version, added as part of a z-stream update,
- **rhel-7-server-rpms** — the repository in which the updated package is located.

The output also shows that we can update the kernel (the kernel package), yum and RPM themselves (the yum and rpm packages), as well as their dependencies (such as the rpm-libs and rpm-python packages), all using the **yum** command.

### 8.1.2. Updating Packages

You can choose to update a single package, multiple packages, or all packages at once. If any dependencies of the package or packages you update have updates available themselves, then they are updated too.

#### Updating a Single Package

To update a single package, run the following command as **root**:

```bash
yum update package_name
```
Example 8.2. Updating the rpm package

To update the rpm package, type:

```
~]# yum update rpm
Loaded plugins: langpacks, product-id, subscription-manager
Updating Red Hat repositories.

Transaction Summary

Upgrade 1 Package (+4 Dependent packages)

Total size: 1.7 M

Is this ok [y/d/N]:

This output contains several items of interest:

1. **Loaded plugins: langpacks, product-id, subscription-manager** — Yum always informs you which yum plug-ins are installed and enabled. See Section 8.6, “Yum Plug-ins” for general information on yum plug-ins, or Section 8.6.3, “Working with Yum”
Plug-ins” for descriptions of specific plug-ins.

2. rpm.x86_64 – you can download and install a new rpm package as well as its dependencies. Transaction check is performed for each of these packages.

3. Yum presents the update information and then prompts you for confirmation of the update; yum runs interactively by default. If you already know which transactions the yum command plans to perform, you can use the -y option to automatically answer yes to any questions that yum asks (in which case it runs non-interactively). However, you should always examine which changes yum plans to make to the system so that you can easily troubleshoot any problems that might arise. You can also choose to download the package without installing it. To do so, select the d option at the download prompt. This launches a background download of the selected package.

If a transaction fails, you can view yum transaction history by using the yum history command as described in Section 8.4, “Working with Transaction History”.

**IMPORTANT**

Yum always installs a new kernel regardless of whether you are using the yum update or yum install command.

When using RPM, on the other hand, it is important to use the rpm -i kernel command which installs a new kernel instead of rpm -u kernel which replaces the current kernel. See Section A.2.1, “Installing and Upgrading Packages” for more information on installing and upgrading kernels with RPM.

Similarly, it is possible to update a package group. Type as root:

```
yum group update group_name
```

Here, replace group_name with a name of the package group you want to update. For more information on package groups, see Section 8.3, “Working with Package Groups”.

Yum also offers the upgrade command that is equal to update with enabled obsoletes configuration option (see Section 8.5.1, “Setting [main] Options”). By default, obsoletes is turned on in /etc/yum.conf, which makes these two commands equivalent.

**Updating All Packages and Their Dependencies**

To update all packages and their dependencies, use the yum update command without any arguments:

```
yum update
```

**Updating Security-Related Packages**

If packages have security updates available, you can update only these packages to their latest versions. Type as root:

```
yum update --security
```

You can also update packages only to versions containing the latest security updates. Type as root:
yum update-minimal --security

For example, assume that:

- the kernel-3.10.0-1 package is installed on your system;
- the kernel-3.10.0-2 package was released as a security update;
- the kernel-3.10.0-3 package was released as a bug fix update.

Then yum update-minimal --security updates the package to kernel-3.10.0-2, and yum update --security updates the package to kernel-3.10.0-3.

8.1.3. Preserving Configuration File Changes

You will inevitably make changes to the configuration files installed by packages as you use your Red Hat Enterprise Linux system. RPM, which yum uses to perform changes to the system, provides a mechanism for ensuring their integrity. See Section A.2.1, “Installing and Upgrading Packages” for details on how to manage changes to configuration files across package upgrades.

8.1.4. Upgrading the System Off-line with ISO and Yum

For systems that are disconnected from the Internet or Red Hat Network, using the yum update command with the Red Hat Enterprise Linux installation ISO image is an easy and quick way to upgrade systems to the latest minor version. The following steps illustrate the upgrading process:

1. Create a target directory to mount your ISO image. This directory is not automatically created when mounting, so create it before proceeding to the next step. As root, type:

   ```
   mkdir mount_dir
   ```

   Replace `mount_dir` with a path to the mount directory. Typically, users create it as a subdirectory in the `/media` directory.

2. Mount the Red Hat Enterprise Linux 7 installation ISO image to the previously created target directory. As root, type:

   ```
   mount -o loop iso_name mount_dir
   ```

   Replace `iso_name` with a path to your ISO image and `mount_dir` with a path to the target directory. Here, the `-o loop` option is required to mount the file as a block device.

3. Copy the `media.repo` file from the mount directory to the `/etc/yum.repos.d/` directory. Note that configuration files in this directory must have the `.repo` extension to function properly.

   ```
   cp mount_dir/media.repo /etc/yum.repos.d/new.repo
   ```

   This creates a configuration file for the yum repository. Replace `new.repo` with the filename, for example `rhel7.repo`.

4. Edit the new configuration file so that it points to the Red Hat Enterprise Linux installation ISO. Add the following line into the `/etc/yum.repos.d/new.repo` file:
Replace `mount_dir` with a path to the mount point.

5. Update all yum repositories including `/etc/yum.repos.d/new.repo` created in previous steps. As `root`, type:

```
yum update
```

This upgrades your system to the version provided by the mounted ISO image.

6. After successful upgrade, you can unmount the ISO image. As `root`, type:

```
umount mount_dir
```

where `mount_dir` is a path to your mount directory. Also, you can remove the mount directory created in the first step. As `root`, type:

```
rmdir mount_dir
```

7. If you will not use the previously created configuration file for another installation or update, you can remove it. As `root`, type:

```
rm /etc/yum.repos.d/new.repo
```

---

**Example 8.3. Upgrading from Red Hat Enterprise Linux 7.0 to 7.1**

If required to upgrade a system without access to the Internet using an ISO image with the newer version of the system, called for example `rhel-server-7.1-x86_64-dvd.iso`, create a target directory for mounting, such as `/media/rhel7/`. As `root`, change into the directory with your ISO image and type:

```
~]# mount -o loop rhel-server-7.1-x86_64-dvd.iso /media/rhel7/
```

Then set up a yum repository for your image by copying the `media.repo` file from the mount directory:

```
~]# cp /media/rhel7/media.repo /etc/yum.repos.d/rhel7.repo
```

To make `yum` recognize the mount point as a repository, add the following line into the `/etc/yum.repos.d/rhel7.repo` copied in the previous step:

```
baseurl=file:///media/rhel7/
```

Now, updating the yum repository will upgrade your system to a version provided by `rhel-server-7.1-x86_64-dvd.iso`. As `root`, execute:

```
~]# yum update
```

When your system is successfully upgraded, you can unmount the image, remove the target directory and the configuration file:
8.2. WORKING WITH PACKAGES

Yum enables you to perform a complete set of operations with software packages, including searching for packages, viewing information about them, installing and removing.

8.2.1. Searching Packages

You can search all RPM package names, descriptions and summaries by using the following command:

```
yum search term...
```

Replace `term` with a package name you want to search.

**Example 8.4. Searching for packages matching a specific string**

To list all packages that match “vim”, “gvim”, or “emacs”, type:

```
$ yum search vim gvim emacs
```

Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager

```
============================= N/S matched: vim
==============================
vim-X11.x86_64 : The VIM version of the vi editor for the X Window System
vim-common.x86_64 : The common files needed by any version of the VIM editor
[output truncated]

============================= N/S matched: emacs
==============================
emacs.x86_64 : GNU Emacs text editor
emacs-auctex.noarch : Enhanced TeX modes for Emacs
[output truncated]
```

Name and summary matches mostly, use "search all" for everything. Warning: No matches found for: gvim

The `yum search` command is useful for searching for packages you do not know the name of, but for which you know a related term. Note that by default, `yum search` returns matches in package name and summary, which makes the search faster. Use the `yum search all` command for a more exhaustive but slower search.

**Filtering the Results**

All of yum's list commands allow you to filter the results by appending one or more `glob expressions` as
arguments. Glob expressions are normal strings of characters which contain one or more of the wildcard characters * (which expands to match any character subset) and ? (which expands to match any single character).

Be careful to escape the glob expressions when passing them as arguments to a `yum` command, otherwise the Bash shell will interpret these expressions as *pathname expansions*, and potentially pass all files in the current directory that match the global expressions to `yum`. To make sure the glob expressions are passed to `yum` as intended, use one of the following methods:

- escape the wildcard characters by preceding them with a backslash character
- double-quote or single-quote the entire glob expression.

Examples in the following section demonstrate usage of both these methods.

### 8.2.2. Listing Packages

To list information on all installed and available packages type the following at a shell prompt:

```
yum list all
```

To list installed and available packages that match inserted glob expressions use the following command:

```
yum list glob_expression...
```

#### Example 8.5. Listing ABRT-related packages

Packages with various ABRT add-ons and plug-ins either begin with “abrt-addon-”, or “abrt-plugin-”. To list these packages, type the following command at a shell prompt. Note how the wildcard characters are escaped with a backslash character:

```
~]$ yum list abrt-addon* abrt-plugin*
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
Installed Packages
abrt-addon-ccpp.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
abrt-addon-kerneloops.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
abrt-addon-pstoreoops.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
abrt-addon-python.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
abrt-addon-vmcore.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
abrt-addon-xorg.x86_64 2.1.11-35.el7
@rhel-7-server-rpms
```

To list all packages installed on your system use the `installed` keyword. The rightmost column in the output lists the repository from which the package was retrieved.

```
yum list installed glob_expression...
```
Example 8.6. Listing all installed versions of the krb package

The following example shows how to list all installed packages that begin with “krb” followed by exactly one character and a hyphen. This is useful when you want to list all versions of certain component as these are distinguished by numbers. The entire glob expression is quoted to ensure proper processing.

```bash
~$ yum list installed "krb?-*"
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
Installed Packages
krb5-libs.x86_64                  1.13.2-10.el7
@rhel-7-server-rpms
```

To list all packages in all enabled repositories that are available to install, use the command in the following form:

```bash
yum list available glob_expression...
```

Example 8.7. Listing available gstreamer plug-ins

For instance, to list all available packages with names that contain “gstreamer” and then “plugin”, run the following command:

```bash
~$ yum list available gstreamer\*plugin\*
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
Available Packages
gstreamer-plugins-bad-free.i686             0.10.23-20.el7
rhel-7-server-rpms
gstreamer-plugins-base.i686                 0.10.36-10.el7
rhel-7-server-rpms
gstreamer-plugins-good.i686                 0.10.31-11.el7
rhel-7-server-rpms
gstreamer1-plugins-bad-free.i686            1.4.5-3.el7
rhel-7-server-rpms
gstreamer1-plugins-base.i686                1.4.5-2.el7
rhel-7-server-rpms
gstreamer1-plugins-base-devel.i686          1.4.5-2.el7
rhel-7-server-rpms
gstreamer1-plugins-base-devel.x86_64        1.4.5-2.el7
rhel-7-server-rpms
gstreamer1-plugins-good.i686                1.4.5-2.el7
rhel-7-server-rpms
gstreamer1-plugins-good.i686                1.4.5-2.el7
rhel-7-server-rpms
```

Listing Repositories

To list the repository ID, name, and number of packages for each enabled repository on your system, use the following command:

```bash
yum repolist
```
To list more information about these repositories, add the `-v` option. With this option enabled, information including the file name, overall size, date of the last update, and base URL are displayed for each listed repository. As an alternative, you can use the `repoinfo` command that produces the same output.

```
$ yum repolist -v
$ yum repoinfo
```

To list both enabled and disabled repositories use the following command. A status column is added to the output list to show which of the repositories are enabled.

```
$ yum repolist all
```

By passing `disabled` as a first argument, you can reduce the command output to disabled repositories. For further specification you can pass the ID or name of repositories or related `glob_expressions` as arguments. Note that if there is an exact match between the repository ID or name and the inserted argument, this repository is listed even if it does not pass the `enabled` or `disabled` filter.

### 8.2.3. Displaying Package Information

To display information about one or more packages, use the following command (glob expressions are valid here as well):

```
$ yum info package_name...
```

Replace `package_name` with the name of the package.

**Example 8.8. Displaying information on the abrt package**

To display information about the `abrt` package, type:

```
$ yum info abrt
```

```
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
Installed Packages
Name : abrt
Arch : x86_64
Version : 2.1.11
Release : 35.el7
Size : 2.3 M
Repo : installed
From repo : rhel-7-server-rpms
Summary : Automatic bug detection and reporting tool
URL : https://fedorahosted.org/abrt/
License : GPLv2+
Description : abrt is a tool to help users to detect defects in applications and to create a bug report with all information needed by maintainer to fix it. It uses plugin system to extend its functionality.
```
The `yum info package_name` command is similar to the `rpm -q --info package_name` command, but provides as additional information the name of the yum repository the RPM package was installed from (look for the `From repo:` line in the output).

**Using yumdb**

You can also query the yum database for alternative and useful information about a package by using the following command:

```
yumdb info package_name
```

This command provides additional information about a package, including the check sum of the package (and the algorithm used to produce it, such as SHA-256), the command given on the command line that was invoked to install the package (if any), and the reason why the package is installed on the system (where `user` indicates it was installed by the user, and `dep` means it was brought in as a dependency).

**Example 8.9. Querying yumdb for information on the yum package**

To display additional information about the `yum` package, type:

```
$ yumdb info yum
```

```
Loaded plugins: langpacks, product-id
yum-3.4.3-132.el7.noarch
  changed_by = 1000
  checksum_data = a9d0510e2ff0d04d04476c693c0313a11379053928efd29561f9a837b3d9eb02
  checksum_type = sha256
  command_line = upgrade
  from_repo = rhel-7-server-rpms
  from_repo_revision = 1449144806
  from_repo_timestamp = 1449144805
  installed_by = 4294967295
  origin_url = https://cdn.redhat.com/content/dist/rhel/server/7/7Server/x86_64/os/Packages/yum-3.4.3-132.el7.noarch.rpm
  reason = user
  releasever = 7Server
  var_uuid = 147a7d49-b60a-429f-8d8f-3ed65e6f4a1
```

For more information on the `yumdb` command, see the `yumdb(8)` manual page.

**8.2.4. Installing Packages**

To install a single package and all of its non-installed dependencies, enter a command in the following form as `root`:

```
yum install package_name
```

You can also install multiple packages simultaneously by appending their names as arguments. To do so, type as `root`:

```
yum install package_name package_name ...
```
If you are installing packages on a *multilib* system, such as an AMD64 or Intel 64 machine, you can specify the architecture of the package (as long as it is available in an enabled repository) by appending `.arch` to the package name:

```
yum install package_name.arch
```

**Example 8.10. Installing packages on multilib system**

To install the `sqlite` package for the *i686* architecture, type:

```
~# yum install sqlite.i686
```

You can use glob expressions to quickly install multiple similarly named packages. Execute as `root`:

```
yum install glob_expression...
```

**Example 8.11. Installing all audacious plugins**

Global expressions are useful when you want to install several packages with similar names. To install all audacious plug-ins, use the command in the following form:

```
~# yum install audacious-plugins- *
```

In addition to package names and glob expressions, you can also provide file names to `yum install`. If you know the name of the binary you want to install, but not its package name, you can give `yum install` the path name. As `root`, type:

```
yum install /usr/sbin/named
```

Yum then searches through its package lists, finds the package which provides `/usr/sbin/named`, if any, and prompts you as to whether you want to install it.

As you can see in the above examples, the `yum install` command does not require strictly defined arguments. It can process various formats of package names and glob expressions, which makes installation easier for users. On the other hand, it takes some time until `yum` parses the input correctly, especially if you specify a large number of packages. To optimize the package search, you can use the following commands to explicitly define how to parse the arguments:

```
yum install-n name

yum install-na name.architecture

yum install-nevra name-epoch:version-release.architecture
```

With `install-n`, `yum` interprets `name` as the exact name of the package. The `install-na` command tells `yum` that the subsequent argument contains the package name and architecture divided by the dot character. With `install-nevra`, `yum` will expect an argument in the form `name-epoch:version-release.architecture`. Similarly, you can use `yum remove-n`, `yum remove-na`, and `yum remove-nevra` when searching for packages to be removed.
NOTE

If you know you want to install the package that contains the named binary, but you do not know in which `bin/` or `sbin/` directory the file is installed, use the `yum provides` command with a glob expression:

```bash
~]# yum provides "*/bin/named"
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
32:bind-9.9.4-14.el7.x86_64 : The Berkeley Internet Name Domain (BIND) DNS (Domain Name System) server
Repo : rhel-7-server-rpms
Matched from: /usr/sbin/named
```

`yum provides "*/file_name"` is a useful way to find the packages that contain `file_name`.

Example 8.12. Installation Process

The following example provides an overview of installation with use of `yum`. To download and install the latest version of the `httpd` package, execute as `root`:

```bash
~]# yum install httpd
Loaded plugins: langpacks, product-id, subscription-manager
Resolving Dependencies
---> Running transaction check
---> Package httpd.x86_64 0:2.4.6-12.el7 will be updated
---> Package httpd.x86_64 0:2.4.6-13.el7 will be an update
--> Processing Dependency: 2.4.6-13.el7 for package: httpd-2.4.6-13.el7.x86_64
---> Running transaction check
---> Package httpd-tools.x86_64 0:2.4.6-12.el7 will be updated
---> Package httpd-tools.x86_64 0:2.4.6-13.el7 will be an update
--> Finished Dependency Resolution

Dependencies Resolved

After executing the above command, `yum` loads the necessary plug-ins and runs the transaction check. In this case, `httpd` is already installed. Since the installed package is older than the latest currently available version, it will be updated. The same applies to the `httpd-tools` package that `httpd` depends on. Then, a transaction summary is displayed:

```
========================================================================
<table>
<thead>
<tr>
<th>Package</th>
<th>Arch</th>
<th>Version</th>
<th>Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Updating:</td>
<td></td>
<td></td>

  httpd.x86_64 0:2.4.6-13.el7

Dependency Updated:
  httpd-tools.x86_64 0:2.4.6-13.el7

Complete!

To install a previously downloaded package from the local directory on your system, use the following command:

```bash
yum localinstall path
```

Replace path with the path to the package you want to install.
8.2.5. Downloading Packages

As shown in Example 8.12, “Installation Process”, at a certain point of installation process you are prompted to confirm the installation with the following message:

...  
Total size: 1.2 M  
Is this ok [y/d/N]:  
...

With the d option, yum downloads the packages without installing them immediately. You can install these packages later offline with the yum localinstall command or you can share them with a different device. Downloaded packages are saved in one of the subdirectories of the cache directory, by default /var/cache/yum/$basearch/$releasever/packages/. The downloading proceeds in background mode so that you can use yum for other operations in parallel.

8.2.6. Removing Packages

Similarly to package installation, yum enables you to uninstall them. To uninstall a particular package, as well as any packages that depend on it, run the following command as root:

yum remove package_name...

As when you install multiple packages, you can remove several at once by adding more package names to the command.

Example 8.13. Removing several packages

To remove totem, type the following at a shell prompt:

~]# yum remove totem

Similar to install, remove can take these arguments:

- package names
- glob expressions
- file lists
- package provides
WARNING
Yum is not able to remove a package without also removing packages which depend on it. This type of operation, which can only be performed by RPM, is not advised, and can potentially leave your system in a non-functioning state or cause applications to not work correctly or crash. For further information, see Section A.2.2, “Uninstalling Packages” in the RPM chapter.

8.3. WORKING WITH PACKAGE GROUPS

A package group is a collection of packages that serve a common purpose, for instance System Tools or Sound and Video. Installing a package group pulls a set of dependent packages, saving time considerably. The yum groups command is a top-level command that covers all the operations that act on package groups in yum.

8.3.1. Listing Package Groups

The summary option is used to view the number of installed groups, available groups, available environment groups, and both installed and available language groups:

```
yum groups summary
```

**Example 8.14. Example output of yum groups summary**

```
~$ yum groups summary
Loaded plugins: langpacks, product-id, subscription-manager
Available Environment Groups: 12
Installed Groups: 10
Available Groups: 12
```

To list all package groups from yum repositories add the list option. You can filter the command output by group names.

```
yum group list glob_expression...
```

Several optional arguments can be passed to this command, including hidden to list also groups not marked as user visible, and ids to list group IDs. You can add language, environment, installed, or available options to reduce the command output to a specific group type.

To list mandatory and optional packages contained in a particular group, use the following command:

```
yum group info glob_expression...
```

**Example 8.15. Viewing information on the LibreOffice package group**

```
~$ yum group info LibreOffice
```
As you can see in the above example, the packages included in the package group can have different states that are marked with the following symbols:

- "-" – Package is not installed and it will not be installed as a part of the package group.
- "+" – Package is not installed but it will be installed on the next `yum upgrade` or `yum group upgrade`.
- "=" – Package is installed and it was installed as a part of the package group.
- `no symbol` – Package is installed but it was installed outside of the package group. This means that the `yum group remove` will not remove these packages.

These distinctions take place only when the `group_command` configuration parameter is set to `objects`, which is the default setting. Set this parameter to a different value if you do not want `yum` to track if a package was installed as a part of the group or separately, which will make "no symbol" packages equivalent to "=" packages.

You can alter the above package states using the `yum group mark` command. For example, `yum group mark packages` marks any given installed packages as members of a specified group. To avoid installation of new packages on group update, use `yum group mark blacklist`. See the `yum(8)` man page for more information on capabilities of `yum group mark`.

**NOTE**

You can identify an environmental group with use of the `@^` prefix and a package group can be marked with `@`. When using `yum group list, info, install, or remove`, pass `@group_name` to specify a package group, `@^group_name` to specify an environmental group, or `group_name` to include both.

### 8.3.2. Installing a Package Group

Each package group has a name and a group ID (`groupid`). To list the names of all package groups, and their group IDs, which are displayed in parentheses, type:
Example 8.16. Finding name and groupid of a package group

To find the name or ID of a package group, for example a group related to the KDE desktop environment, type:

```bash
~$ yum group list ids kde*
Available environment groups:
    KDE Plasma Workspaces (kde-desktop-environment)
Done
```

Some groups are hidden by settings in the configured repositories. For example, on a server, make use of the `hidden` command option to list hidden groups too:

```bash
~$ yum group list hidden ids kde*
Loaded plugins: product-id, subscription-manager
Available Groups:
    KDE (kde-desktop)
Done
```

You can install a package group by passing its full group name, without the groupid part, to the `group install` command. As `root`, type:

```bash
yum group install "group name"
```

You can also install by groupid. As `root`, execute the following command:

```bash
yum group install groupid
```

You can pass the groupid or quoted group name to the `install` command if you prepend it with an `@` symbol, which tells `yum` that you want to perform `group install`. As `root`, type:

```bash
yum install @group
```

Replace `group` with the groupid or quoted group name. The same logic applies to environmental groups:

```bash
yum install @^group
```

Example 8.17. Four equivalent ways of installing the KDE Desktop group

As mentioned before, you can use four alternative, but equivalent ways to install a package group. For KDE Desktop, the commands look as follows:

```bash
~# yum group install "KDE Desktop"
~# yum group install kde-desktop
~# yum install @"KDE Desktop"
~# yum install @kde-desktop
```
8.3.3. Removing a Package Group

You can remove a package group using syntax similar to the `install` syntax, with use of either name of the package group or its id. As `root`, type:

```bash
yum group remove group_name
yum group remove groupid
```

Also, you can pass the groupid or quoted name to the `remove` command if you prepend it with an `@` symbol, which tells yum that you want to perform `group remove`. As `root`, type:

```bash
yum remove @group
```

Replace `group` with the groupid or quoted group name. Similarly, you can replace an environmental group:

```bash
yum remove @^group
```

**Example 8.18. Four equivalent ways of removing the KDE Desktop group**

Similarly to install, you can use four alternative, but equivalent ways to remove a package group. For KDE Desktop, the commands look as follows:

```bash
~]# yum group remove "KDE Desktop"
~]# yum group remove kde-desktop
~]# yum remove @"KDE Desktop"
~]# yum remove @kde-desktop
```

8.4. WORKING WITH TRANSACTION HISTORY

The `yum history` command enables users to review information about a timeline of yum transactions, the dates and times they occurred, the number of packages affected, whether these transactions succeeded or were aborted, and if the RPM database was changed between transactions. Additionally, this command can be used to undo or redo certain transactions. All history data is stored in the `history DB in the /var/lib/yum/history/` directory.

8.4.1. Listing Transactions

To display a list of the twenty most recent transactions, as `root`, either run `yum history` with no additional arguments, or type the following at a shell prompt:

```bash
yum history list
```

To display all transactions, add the `all` keyword:

```bash
yum history list all
```

To display only transactions in a given range, use the command in the following form:
**yum history list** *start_id..end_id*

You can also list only transactions regarding a particular package or packages. To do so, use the command with a package name or a glob expression:

**yum history list** *glob_expression...*

**Example 8.19. Listing the five oldest transactions**

In the output of **yum history list**, the most recent transaction is displayed at the top of the list. To display information about the five oldest transactions stored in the history database, type:

```
~]# yum history list 1..5
```

```
Loaded plugins: langpacks, product-id, subscription-manager

<table>
<thead>
<tr>
<th>ID</th>
<th>Login user</th>
<th>Date and time</th>
<th>Action(s)</th>
<th>Altered</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>User &lt;user&gt;</td>
<td>2013-07-29 15:33</td>
<td>Install</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>User &lt;user&gt;</td>
<td>2013-07-21 15:10</td>
<td>Install</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>User &lt;user&gt;</td>
<td>2013-07-16 15:27</td>
<td>I, U</td>
<td>73</td>
</tr>
<tr>
<td>2</td>
<td>System &lt;unset&gt;</td>
<td>2013-07-16 15:19</td>
<td>Update</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>System &lt;unset&gt;</td>
<td>2013-07-16 14:38</td>
<td>Install</td>
<td></td>
</tr>
</tbody>
</table>
```

All forms of the **yum history list** command produce tabular output with each row consisting of the following columns:

- **ID** – an integer value that identifies a particular transaction.
- **Login user** – the name of the user whose login session was used to initiate a transaction. This information is typically presented in the *Full Name <username>* form. For transactions that were not issued by a user (such as an automatic system update), *System <unset>* is used instead.
- **Date and time** – the date and time when a transaction was issued.
- **Action(s)** – a list of actions that were performed during a transaction as described in **Table 8.1**, “Possible values of the Action(s) field”.
- **Altered** – the number of packages that were affected by a transaction, possibly followed by additional information as described in **Table 8.2**, “Possible values of the Altered field”.

**Table 8.1. Possible values of the Action(s) field**
<table>
<thead>
<tr>
<th>Action</th>
<th>Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Downgrade</td>
<td>D</td>
<td>At least one package has been downgraded to an older version.</td>
</tr>
<tr>
<td>Erase</td>
<td>E</td>
<td>At least one package has been removed.</td>
</tr>
<tr>
<td>Install</td>
<td>I</td>
<td>At least one new package has been installed.</td>
</tr>
<tr>
<td>Obsoleting</td>
<td>O</td>
<td>At least one package has been marked as obsolete.</td>
</tr>
<tr>
<td>Reinstall</td>
<td>R</td>
<td>At least one package has been reinstalled.</td>
</tr>
<tr>
<td>Update</td>
<td>U</td>
<td>At least one package has been updated to a newer version.</td>
</tr>
</tbody>
</table>

Table 8.2. Possible values of the Altered field

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>Before the transaction finished, the <code>rpmdb</code> database was changed outside yum.</td>
</tr>
<tr>
<td>&gt;</td>
<td>After the transaction finished, the <code>rpmdb</code> database was changed outside yum.</td>
</tr>
<tr>
<td>*</td>
<td>The transaction failed to finish.</td>
</tr>
<tr>
<td>#</td>
<td>The transaction finished successfully, but yum returned a non-zero exit code.</td>
</tr>
<tr>
<td>E</td>
<td>The transaction finished successfully, but an error or a warning was displayed.</td>
</tr>
<tr>
<td>P</td>
<td>The transaction finished successfully, but problems already existed in the <code>rpmdb</code> database.</td>
</tr>
<tr>
<td>S</td>
<td>The transaction finished successfully, but the <code>--skip-broken</code> command-line option was used and certain packages were skipped.</td>
</tr>
</tbody>
</table>

To synchronize the `rpmdb` or `yumdb` database contents for any installed package with the currently used `rpmdb` or `yumdb` database, type the following:

```
yum history sync
```

To display some overall statistics about the currently used history database use the following command:

```
yum history stats
```

Example 8.20. Example output of yum history stats
Yum also enables you to display a summary of all past transactions. To do so, run the command in the following form as `root`:

```bash
yum history summary
```

To display only transactions in a given range, type:

```bash
yum history summary start_id..end_id
```

Similarly to the `yum history list` command, you can also display a summary of transactions regarding a certain package or packages by supplying a package name or a glob expression:

```bash
yum history summary glob_expression...
```

**Example 8.21. Summary of the five latest transactions**

```bash
~]# yum history summary 1..5
Loaded plugins: langpacks, product-id, subscription-manager
Login user | Time       | Action(s) |
---------- |------------|-----------|
Altered   |-------------|-----------|
-----------
Jaromir ... <jhradilek> | Last day   | Install   |
1          |            |           |
Jaromir ... <jhradilek> | Last week  | Install   |
1          |            |           |
Jaromir ... <jhradilek> | Last 2 weeks | I, U   |
73         |            |           |
System <unset> | Last 2 weeks | I, U   |
1107       |            |           |
```

All forms of the `yum history summary` command produce simplified tabular output similar to the output of `yum history list`. 
As shown above, both `yum history list` and `yum history summary` are oriented towards transactions, and although they allow you to display only transactions related to a given package or packages, they lack important details, such as package versions. To list transactions from the perspective of a package, run the following command as `root`:

```
yum history package-list glob_expression...
```

**Example 8.22. Tracing the history of a package**

For example, to trace the history of `subscription-manager` and related packages, type the following at a shell prompt:

```
~]# yum history package-list subscription-manager
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
ID     | Action(s)      | Package
-----------------------------------------------
2 | Updated        | subscription-manager-1.13.22-1.el7.x86_64
EE 2 | Update         | 1.15.9-15.el7.x86_64
EE 2 | Obsoleted      | subscription-manager-firstboot-1.13.22-1.el7.x86_64
EE 2 | Updated        | subscription-manager-gui-1.13.22-1.el7.x86_64
EE 2 | Update         | 1.15.9-15.el7.x86_64
EE 2 | Obsoleting     | subscription-manager-initial-setup-addon-1.15.9-15.el7.x86_64
EE 1 | Install        | subscription-manager-1.13.22-1.el7.x86_64
EE 1 | Install        | subscription-manager-firstboot-1.13.22-1.el7.x86_64
EE 1 | Install        | subscription-manager-gui-1.13.22-1.el7.x86_64
history package-list
```

In this example, three packages were installed during the initial system installation: `subscription-manager`, `subscription-manager-firstboot`, and `subscription-manager-gui`. In the third transaction, all these packages were updated from version 1.10.11 to version 1.10.17.

### 8.4.2. Examining Transactions

To display the summary of a single transaction, as `root`, use the `yum history summary` command in the following form:

```
yum history summary id
```

Here, `id` stands for the ID of the transaction.

To examine a particular transaction or transactions in more detail, run the following command as `root`:

```
yum history info id...
```
The `id` argument is optional and when you omit it, yum automatically uses the last transaction. Note that when specifying more than one transaction, you can also use a range:

```
yum history info start_id..end_id
```

**Example 8.23. Example output of yum history info**

The following is sample output for two transactions, each installing one new package:

```
~]# yum history info 4..5
Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
Transaction ID : 4..5
Begin time     : Mon Dec  7 16:51:07 2015
Begin rpmdb    : 1252:d2b62b7b5768e855723954852fd7e55f641fbad9
End time       :            17:18:49 2015 (27 minutes)
End rpmdb      : 1253:cf8449dc4c53fc0cbbc0a4c48e496a6c50f3d43c5
User           : Maxim Svistunov <msvistun>
Return-Code    : Success
Command Line   : install tigervnc-server.x86_64
Command Line   : reinstall tigervnc-server
Transaction performed with:
  Installed     rpm-4.11.3-17.el7.x86_64                  @rhel-7-server-rpms
  Installed     subscription-manager-1.15.9-15.el7.x86_64 @rhel-7-server-rpms
  Installed     yum-3.4.3-132.el7.noarch                  @rhel-7-server-rpms
Packages Altered:
  Reinstall tigervnc-server-1.3.1-3.el7.x86_64 @rhel-7-server-rpms
history info
```

You can also view additional information, such as what configuration options were used at the time of the transaction, or from what repository and why were certain packages installed. To determine what additional information is available for a certain transaction, type the following at a shell prompt as root:

```
yum history addon-info id
```

Similarly to `yum history info`, when no `id` is provided, yum automatically uses the latest transaction. Another way to refer to the latest transaction is to use the `last` keyword:

```
yum history addon-info last
```

**Example 8.24. Example output of yum history addon-info**

For the fourth transaction in the history, the `yum history addon-info` command provides the following output:

```
~]# yum history addon-info 4
Loaded plugins: langpacks, product-id, subscription-manager
```
In the output of the `yum history addon-info` command, three types of information are available:

- **config-main** – global yum options that were in use during the transaction. See Section 8.5.1, “Setting [main] Options” for information on how to change global options.

- **config-repos** – options for individual yum repositories. See Section 8.5.2, “Setting [repository] Options” for information on how to change options for individual repositories.

- **saved_tx** – the data that can be used by the `yum load-transaction` command in order to repeat the transaction on another machine (see below).

To display a selected type of additional information, run the following command as `root`:

```
yum history addon-info id information
```

### 8.4.3. Reverting and Repeating Transactions

Apart from reviewing the transaction history, the `yum history` command provides means to revert or repeat a selected transaction. To revert a transaction, type the following at a shell prompt as `root`:

```
yum history undo id
```

To repeat a particular transaction, as `root`, run the following command:

```
yum history redo id
```

Both commands also accept the `last` keyword to undo or repeat the latest transaction.

Note that both `yum history undo` and `yum history redo` commands only revert or repeat the steps that were performed during a transaction. If the transaction installed a new package, the `yum history undo` command will uninstall it, and if the transaction uninstalled a package the command will again install it. This command also attempts to downgrade all updated packages to their previous version, if these older packages are still available.

When managing several identical systems, yum also enables you to perform a transaction on one of them, store the transaction details in a file, and after a period of testing, repeat the same transaction on the remaining systems as well. To store the transaction details to a file, type the following at a shell prompt as `root`:

```
yum -q history addon-info id saved_tx > file_name
```

Once you copy this file to the target system, you can repeat the transaction by using the following command as `root`:
yum load-transaction file_name

You can configure load-transaction to ignore missing packages or rpmdb version. For more information on these configuration options see the yum.conf(5) man page.

8.4.4. Starting New Transaction History

Yum stores the transaction history in a single SQLite database file. To start new transaction history, run the following command as root:

```bash
yum history new
```

This will create a new, empty database file in the /var/lib/yum/history/ directory. The old transaction history will be kept, but will not be accessible as long as a newer database file is present in the directory.

8.5. CONFIGURING YUM AND YUM REPOSITORIES

**NOTE**

To expand your expertise, you might also be interested in the Red Hat System Administration III (RH254) and RHCSA Rapid Track (RH199) training courses.

The configuration information for yum and related utilities is located at /etc/yum.conf. This file contains one mandatory [main] section, which enables you to set yum options that have global effect, and can also contain one or more [repository] sections, which allow you to set repository-specific options. However, it is recommended to define individual repositories in new or existing .repo files in the /etc/yum.repos.d/ directory. The values you define in individual [repository] sections of the /etc/yum.conf file override values set in the [main] section.

This section shows you how to:

- set global yum options by editing the [main] section of the /etc/yum.conf configuration file;
- set options for individual repositories by editing the [repository] sections in /etc/yum.conf and .repo files in the /etc/yum.repos.d/ directory;
- use yum variables in /etc/yum.conf and files in the /etc/yum.repos.d/ directory so that dynamic version and architecture values are handled correctly;
- add, enable, and disable yum repositories on the command line; and
- set up your own custom yum repository.

8.5.1. Setting [main] Options

The /etc/yum.conf configuration file contains exactly one [main] section, and while some of the key-value pairs in this section affect how yum operates, others affect how yum treats repositories. You can add many additional options under the [main] section heading in /etc/yum.conf.

A sample /etc/yum.conf configuration file can look like this:
The following are the most commonly used options in the `[main]` section:

`assumeyes=value`

The `assumeyes` option determines whether or not `yum` prompts for confirmation of critical actions. Replace `value` with one of:

- `0` (*default*) — `yum` prompts for confirmation of critical actions it performs.
- `1` — Do not prompt for confirmation of critical `yum` actions. If `assumeyes=1` is set, `yum` behaves in the same way as the command-line options `-y` and `--assumeyes`.

`cachedir=directory`

Use this option to set the directory where `yum` stores its cache and database files. Replace `directory` with an absolute path to the directory. By default, `yum`'s cache directory is `/var/cache/yum/$basearch/$releasever/`.

See Section 8.5.3, “Using Yum Variables” for descriptions of the `$basearch` and `$releasever` `yum` variables.

`debuglevel=value`

This option specifies the detail of debugging output produced by `yum`. Here, `value` is an integer between `1` and `10`. Setting a higher `debuglevel` value causes `yum` to display more detailed debugging output. `debuglevel=2` is the default, while `debuglevel=0` disables debugging output.

`exactarch=value`

With this option, you can set `yum` to consider the exact architecture when updating already installed packages. Replace `value` with:

- `0` — Do not take into account the exact architecture when updating packages.
- `1` (*default*) — Consider the exact architecture when updating packages. With this setting, `yum` does not install a package for 32-bit architecture to update a package already installed on the system with 64-bit architecture.

`exclude=package_name[more_package_names]`
The `exclude` option enables you to exclude packages by keyword during installation or system update. Listing multiple packages for exclusion can be accomplished by quoting a space-delimited list of packages. Shell glob expressions using wildcards (for example, `*` and `?`) are allowed.

**gpgcheck=value**

Use the `gpgcheck` option to specify if yum should perform a GPG signature check on packages. Replace `value` with:

- `0` — Disable GPG signature-checking on packages in all repositories, including local package installation.
- `1 (default)` — Enable checking of GPG signature on all packages in all repositories, including local package installation. With `gpgcheck` enabled, all packages' signatures are checked.

If this option is set in the `[main]` section of the `/etc/yum.conf` file, it sets the GPG-checking rule for all repositories. However, you can also set `gpgcheck=value` for individual repositories instead; that is, you can enable GPG-checking on one repository while disabling it on another. Setting `gpgcheck=value` for an individual repository in its corresponding `.repo` file overrides the default if it is present in `/etc/yum.conf`.

For more information on GPG signature-checking, see Section A.3.2, “Checking Package Signatures”.

**group_command=value**

Use the `group_command` option to specify how the `yum group install`, `yum group upgrade`, and `yum group remove` commands handle a package group. Replace `value` with one of:

- `simple` — Install all members of a package group. Upgrade only previously installed packages, but do not install packages that have been added to the group in the meantime.
- `compat` — Similar to `simple` but `yum upgrade` also installs packages that were added to the group since the previous upgrade.
- `objects` — (default) With this option, yum keeps track of the previously installed groups and distinguishes between packages installed as a part of the group and packages installed separately. See Example 8.15, “Viewing information on the LibreOffice package group”

**group_package_types=package_type[more_package_types]**

Here you can specify which type of packages (optional, default or mandatory) is installed when the `yum group install` command is called. The `default` and `mandatory` package types are chosen by default.

**history_record=value**

With this option, you can set yum to record transaction history. Replace `value` with one of:

- `0` — yum should not record history entries for transactions.
- `1 (default)` — yum should record history entries for transactions. This operation takes certain amount of disk space, and some extra time in the transactions, but it provides a lot of information about past operations, which can be displayed with the `yum history` command.

`history_record=1` is the default.
For more information on the `yum history` command, see Section 8.4, “Working with Transaction History”.

**NOTE**

Yum uses history records to detect modifications to the rpmdb data base that have been done outside of yum. In such case, yum displays a warning and automatically searches for possible problems caused by altering rpmdb. With `history_record` turned off, yum is not able to detect these changes and no automatic checks are performed.

`installonlypkgs`=

*space separated list of packages*

Here you can provide a space-separated list of packages which yum can *install*, but will never *update*. See the `yum.conf(5)` manual page for the list of packages which are install-only by default.

If you add the `installonlypkgs` directive to `/etc/yum.conf`, you should ensure that you list all of the packages that should be install-only, including any of those listed under the `installonlypkgs` section of `yum.conf(5)`. In particular, kernel packages should always be listed in `installonlypkgs` (as they are by default), and `installonly_limit` should always be set to a value greater than 2 so that a backup kernel is always available in case the default one fails to boot.

`installonly_limit=value`

This option sets how many packages listed in the `installonlypkgs` directive can be installed at the same time. Replace *value* with an integer representing the maximum number of versions that can be installed simultaneously for any single package listed in `installonlypkgs`.

The defaults for the `installonlypkgs` directive include several different kernel packages, so be aware that changing the value of `installonly_limit` also affects the maximum number of installed versions of any single kernel package. The default value listed in `/etc/yum.conf` is `installonly_limit=3`, and it is not recommended to decrease this value, particularly below 2.

`keepcache=value`

The `keepcache` option determines whether yum keeps the cache of headers and packages after successful installation. Here, *value* is one of:

0 *(default)* — Do not retain the cache of headers and packages after a successful installation.

1 — Retain the cache after a successful installation.

`logfile=file_name`

To specify the location for logging output, replace *file_name* with an absolute path to the file in which yum should write its logging output. By default, yum logs to `/var/log/yum.log`.

`max_connenctions=number`

Here *value* stands for the maximum number of simultaneous connections, default is 5.

`multilib_policy=value`

The `multilib_policy` option sets the installation behavior if several architecture versions are available for package install. Here, *value* stands for:
best – install the best-choice architecture for this system. For example, setting multilib_policy=best on an AMD64 system causes yum to install the 64-bit versions of all packages.

all – always install every possible architecture for every package. For example, with multilib_policy set to all on an AMD64 system, yum would install both the i686 and AMD64 versions of a package, if both were available.

obsoletes=value

The obsoletes option enables the obsoletes process logic during updates. When one package declares in its spec file that it obsoletes another package, the latter package is replaced by the former package when the former package is installed. Obsoletes are declared, for example, when a package is renamed. Replace value with one of:

0 – Disable yum's obsoletes processing logic when performing updates.

1 (default) – Enable yum's obsoletes processing logic when performing updates.

plugins=value

This is a global switch to enable or disable yum plug-ins, value is one of:

0 – Disable all yum plug-ins globally.

1 (default) – Enable all yum plug-ins globally. With plugins=1, you can still disable a specific yum plug-in by setting enabled=0 in that plug-in’s configuration file.

For more information about various yum plug-ins, see Section 8.6, “Yum Plug-ins”. For further information on controlling plug-ins, see Section 8.6.1, “Enabling, Configuring, and Disabling Yum Plug-ins”.

reposdir=directory

Here, directory is an absolute path to the directory where .repo files are located. All .repo files contain repository information (similar to the [repository] sections of /etc/yum.conf). Yum collects all repository information from .repo files and the [repository] section of the /etc/yum.conf file to create a master list of repositories to use for transactions. If reposdir is not set, yum uses the default directory /etc/yum.repos.d/.

retries=value

This option sets the number of times yum should attempt to retrieve a file before returning an error. value is an integer 0 or greater. Setting value to 0 makes yum retry forever. The default value is 10.

For a complete list of available [main] options, see the [main] OPTIONS section of the yum.conf(5) manual page.
8.5.2. Setting [repository] Options

The [repository] sections, where repository is a unique repository ID such as my_personal_repo (spaces are not permitted), allow you to define individual yum repositories. To avoid conflicts, custom repositories should not use names used by Red Hat repositories.

The following is a bare minimum example of the form a [repository] section takes:

```
[repository]
name=repository_name
baseurl=repository_url
```

Every [repository] section must contain the following directives:

`name=repository_name`

Here, repository_name is a human-readable string describing the repository.

`baseurl=repository_url`

Replace repository_url with a URL to the directory where the repodata directory of a repository is located:

- If the repository is available over HTTP, use: `http://path/to/repo`
- If the repository is available over FTP, use: `ftp://path/to/repo`
- If the repository is local to the machine, use: `file:///path/to/local/repo`
- If a specific online repository requires basic HTTP authentication, you can specify your user name and password by prepending it to the URL as `username:password@link`. For example, if a repository on `http://www.example.com/repo/` requires a user name of “user” and a password of “password”, then the baseurl link could be specified as `http://user:password@www.example.com/repo/`.

Usually this URL is an HTTP link, such as:

```
baseurl=http://path/to/repo/releases/$releasever/server/$basearch/os/
```

Note that yum always expands the $releasever, $arch, and $basearch variables in URLs. For more information about yum variables, see Section 8.5.3, “Using Yum Variables”.

Other useful [repository] directive are:

`enabled=value`

This is a simple way to tell yum to use or ignore a particular repository, value is one of:

0 — Do not include this repository as a package source when performing updates and installs. This is an easy way of quickly turning repositories on and off, which is useful when you desire a single package from a repository that you do not want to enable for updates or installs.

1 — Include this repository as a package source.
Turning repositories on and off can also be performed by passing either the `--enablerepo=repo_name` or `--disablerepo=repo_name` option to `yum`, or through the Add/Remove Software window of the PackageKit utility.

async=value

Controls parallel downloading of repository packages. Here, value is one of:

- auto (default) – parallel downloading is used if possible, which means that `yum` automatically disables it for repositories created by plug-ins to avoid failures.
- on – parallel downloading is enabled for the repository.
- off – parallel downloading is disabled for the repository.

Many more [repository] options exist, part of them have the same form and function as certain [main] options. For a complete list, see the [repository] OPTIONS section of the `yum.conf` manual page.

Example 8.25. A sample /etc/yum.repos.d/redhat.repo file

The following is a sample /etc/yum.repos.d/redhat.repo file:

```ini
# # Red Hat Repositories
# Managed by (rhsm) subscription-manager
#
[red-hat-enterprise-linux-scalable-file-system-for-rhel-6-entitlement-rpms]
name = Red Hat Enterprise Linux Scalable File System (for RHEL 6 Entitlement) (RPMs)
baseurl = https://cdn.redhat.com/content/dist/rhel/entitlement-6/releases/$releasever/$basearch/scalablefilesystem/os
enabled = 1
gpgcheck = 1
gpgkey = file:///etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
sslverify = 1
sslcacert = /etc/rhsm/ca/redhat-uep.pem
sslcclientkey = /etc/pki/entitlement/key.pem
sslcclientcert = /etc/pki/entitlement/11300387955690106.pem

[red-hat-enterprise-linux-scalable-file-system-for-rhel-6-entitlement-source-rpms]
name = Red Hat Enterprise Linux Scalable File System (for RHEL 6 Entitlement) (Source RPMs)
baseurl = https://cdn.redhat.com/content/dist/rhel/entitlement-6/releases/$releasever/$basearch/scalablefilesystem/source/SRPMS
enabled = 0
gpgcheck = 1
gpgkey = file:///etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
sslverify = 1
sslcacert = /etc/rhsm/ca/redhat-uep.pem
sslcclientkey = /etc/pki/entitlement/key.pem
sslcclientcert = /etc/pki/entitlement/11300387955690106.pem
```
8.5.3. Using Yum Variables

You can use and reference the following built-in variables in yum commands and in all yum configuration files (that is, /etc/yum.conf and all .repo files in the /etc/yum.repos.d/ directory):

$releasever

You can use this variable to reference the release version of Red Hat Enterprise Linux. Yum obtains the value of $releasever from the distroverpkg=value line in the /etc/yum.conf configuration file. If there is no such line in /etc/yum.conf, then yum infers the correct value by deriving the version number from the redhat-release product package that provides the redhat-release file.

$arch

You can use this variable to refer to the system's CPU architecture as returned when calling Python's os.uname() function. Valid values for $arch include: i586, i686 and x86_64.

$basearch

You can use $basearch to reference the base architecture of the system. For example, i686 and i586 machines both have a base architecture of i386, and AMD64 and Intel 64 machines have a base architecture of x86_64.

$YUM0-9

These ten variables are each replaced with the value of any shell environment variables with the same name. If one of these variables is referenced (in /etc/yum.conf for example) and a shell environment variable with the same name does not exist, then the configuration file variable is not replaced.

To define a custom variable or to override the value of an existing one, create a file with the same name as the variable (without the “$” sign) in the /etc/yum/vars/ directory, and add the desired value on its first line.

For example, repository descriptions often include the operating system name. To define a new variable called $osname, create a new file with “Red Hat Enterprise Linux” on the first line and save it as /etc/yum/vars/osname:
Instead of “Red Hat Enterprise Linux 7”, you can now use the following in the .repo files:

```bash
name=$osname $releasever
```

### 8.5.4. Viewing the Current Configuration

To display the current values of global yum options (that is, the options specified in the `[main]` section of the `/etc/yum.conf` file), execute the `yum-config-manager` command with no command-line options:

```
yum-config-manager
```

To list the content of a different configuration section or sections, use the command in the following form:

```
yum-config-manager section...
```

You can also use a glob expression to display the configuration of all matching sections:

```
yum-config-manager glob_expression...
```

#### Example 8.26. Viewing configuration of the main section

To list all configuration options and their corresponding values for the main section, type the following at a shell prompt:

```
~]$ yum-config-manager main *
Loaded plugins: langpacks, product-id, subscription-manager
================================== main
===================================
[main]
alwaysprompt = True
assumeyes = False
bandwith = 0
bugtracker_url = https://bugzilla.redhat.com/enter_bug.cgi?
product=Red%20Hat%20Enterprise%20Red%20Hat%20Enterprise%206&component=yum
cache = 0
[output truncated]
```

### 8.5.5. Adding, Enabling, and Disabling a Yum Repository

**NOTE**

To expand your expertise, you might also be interested in the Red Hat System Administration III (RH254) training course.

Section 8.5.2, “Setting [repository] Options” describes various options you can use to define a yum repository. This section explains how to add, enable, and disable a repository by using the `yum-
config-manager command.

**IMPORTANT**

When the system is registered with Red Hat Subscription Management to the certificate-based Content Delivery Network (CDN), the Red Hat Subscription Manager tools are used to manage repositories in the /etc/yum.repos.d/redhat.repo file.

Adding a Yum Repository
To define a new repository, you can either add a [repository] section to the /etc/yum.conf file, or to a .repo file in the /etc/yum.repos.d/ directory. All files with the .repo file extension in this directory are read by yum, and it is recommended to define your repositories here instead of in /etc/yum.conf.

**WARNING**

Obtaining and installing software packages from unverified or untrusted software sources other than Red Hat's certificate-based Content Delivery Network (CDN) constitutes a potential security risk, and could lead to security, stability, compatibility, and maintainability issues.

Yum repositories commonly provide their own .repo file. To add such a repository to your system and enable it, run the following command as root:

```
$ yum-config-manager --add-repo repository_url
```

...where repository_url is a link to the .repo file.

**Example 8.27. Adding example.repo**

To add a repository located at http://www.example.com/example.repo, type the following at a shell prompt:

```
~]# yum-config-manager --add-repo http://www.example.com/example.repo
Loaded plugins: langpacks, product-id, subscription-manager
adding repo from: http://www.example.com/example.repo
grabbing file http://www.example.com/example.repo to 
/etc/yum.repos.d/example.repo
example.repo                                          | 413 B
00:00
repo saved to /etc/yum.repos.d/example.repo
```

Enabling a Yum Repository
To enable a particular repository or repositories, type the following at a shell prompt as root:
yum-config-manager --enable repository...

...where repository is the unique repository ID (use yum repolist all to list available repository IDs). Alternatively, you can use a glob expression to enable all matching repositories:

yum-config-manager --enable glob_expression...

Example 8.28. Enabling repositories defined in custom sections of /etc/yum.conf.

To enable repositories defined in the [example], [example-debuginfo], and [example-source] sections, type:

```bash
~# yum-config-manager --enable example*
```

Loaded plugins: langpacks, product-id, subscription-manager
============================== repo: example
[example]
bandwidth = 0
base_persistdir = /var/lib/yum/repos/x86_64/7Server
baseurl = http://www.example.com/repo/7Server/x86_64/
cache = 0
cachedir = /var/cache/yum/x86_64/7Server/example
[output truncated]

Example 8.29. Enabling all repositories

To enable all repositories defined both in the /etc/yum.conf file and in the /etc/yum.repos.d/ directory, type:

```bash
~# yum-config-manager --enable *
```

Loaded plugins: langpacks, product-id, subscription-manager
============================== repo: example
[example]
bandwidth = 0
base_persistdir = /var/lib/yum/repos/x86_64/7Server
baseurl = http://www.example.com/repo/7Server/x86_64/
cache = 0
cachedir = /var/cache/yum/x86_64/7Server/example
[output truncated]

When successful, the yum-config-manager --enable command displays the current repository configuration.

Disabling a Yum Repository

To disable a yum repository, run the following command as root:

```bash
yum-config-manager --disable repository...
```
...where repository is the unique repository ID (use `yum repolist all` to list available repository IDs). Similarly to `yum-config-manager --enable`, you can use a glob expression to disable all matching repositories at the same time:

```
yum-config-manager --disable glob_expression...
```

Example 8.30. Disabling all repositories

To disable all repositories defined both in the `/etc/yum.conf` file and in the `/etc/yum.repos.d/` directory, type:

```
~]# yum-config-manager --disable 
Loaded plugins: langpacks, product-id, subscription-manager
================================ repo: example
================================
[example]
bandwidth = 0
base_persistdir = /var/lib/yum/repos/x86_64/7Server
baseurl = http://www.example.com/repo/7Server/x86_64/
cache = 0
cachedir = /var/cache/yum/x86_64/7Server/example
[output truncated]
```

When successful, the `yum-config-manager --disable` command displays the current configuration.

8.5.6. Creating a Yum Repository

To set up a yum repository, follow these steps:

1. Install the `createrepo` package. To do so, type the following at a shell prompt as root:

```
yum install createrepo
```

2. Copy all packages that you want to have in your repository into one directory, such as `/mnt/local_repo/`.

3. Change to this directory and run the following command:

```
createrepo --database /mnt/local_repo
```

This creates the necessary metadata for your yum repository, as well as the sqlite database for speeding up yum operations.

8.5.7. Adding the Optional and Supplementary Repositories

The Optional and Supplementary subscription channels provide additional software packages for Red Hat Enterprise Linux that cover open source licensed software (in the Optional channel) and proprietary licensed software (in the Supplementary channel).

Before subscribing to the Optional and Supplementary channels see the Scope of Coverage Details. If you decide to install packages from these channels, follow the steps documented in the article called
How to access Optional and Supplementary channels, and -devel packages using Red Hat Subscription Manager (RHSM)? on the Red Hat Customer Portal.

8.6. YUM PLUG-INS

Yum provides plug-ins that extend and enhance its operations. Certain plug-ins are installed by default. Yum always informs you which plug-ins, if any, are loaded and active whenever you call any yum command. For example:

```
[main]#
]# yum info yum
Loaded plugins: langpacks, product-id, subscription-manager
[output truncated]
```

Note that the plug-in names which follow `Loaded plugins:` are the names you can provide to the `--disableplugin=` option.

8.6.1. Enabling, Configuring, and Disabling Yum Plug-ins

To enable yum plug-ins, ensure that a line beginning with `plugins=` is present in the `[main]` section of `/etc/yum.conf`, and that its value is `1`:

```
plugins=1
```

You can disable all plug-ins by changing this line to `plugins=0`.

**IMPORTANT**

Disabling all plug-ins is not advised because certain plug-ins provide important yum services. In particular, the `product-id` and `subscription-manager` plug-ins provide support for the certificate-based Content Delivery Network (CDN). Disabling plug-ins globally is provided as a convenience option, and is generally only recommended when diagnosing a potential problem with yum.

Every installed plug-in has its own configuration file in the `/etc/yum/pluginconf.d/` directory. You can set plug-in specific options in these files. For example, here is the `aliases` plug-in's `aliases.conf` configuration file:

```
[main]
enabled=1
```

Similar to the `/etc/yum.conf` file, the plug-in configuration files always contain a `[main]` section where the `enabled=` option controls whether the plug-in is enabled when you run `yum` commands. If this option is missing, you can add it manually to the file.

If you disable all plug-ins by setting `enabled=0` in `/etc/yum.conf`, then all plug-ins are disabled regardless of whether they are enabled in their individual configuration files.

If you merely want to disable all yum plug-ins for a single `yum` command, use the `--noplugins` option.

If you want to disable one or more yum plug-ins for a single `yum` command, add the `--disableplugin=` option to the command. For example, to disable the `aliases` plug-in while updating a system, type:
The plug-in names you provide to the --disableplugin= option are the same names listed after the Loaded plugins line in the output of any yum command. You can disable multiple plug-ins by separating their names with commas. In addition, you can match multiple plug-in names or shorten long ones by using glob expressions:

```bash
-]# yum update --disableplugin=aliases,lang*
```

### 8.6.2. Installing Additional Yum Plug-ins

Yum plug-ins usually adhere to the `yum-plugin-plugin_name` package-naming convention, but not always: the package which provides the `kabi` plug-in is named `kabi-yum-plugins`, for example. You can install a yum plug-in in the same way you install other packages. For instance, to install the `yum-aliases` plug-in, type the following at a shell prompt:

```bash
-]# yum install yum-plugin-aliases
```

### 8.6.3. Working with Yum Plug-ins

The following list provides descriptions and usage instructions for several useful yum plug-ins. Plug-ins are listed by names, brackets contain the name of the package.

**search-disabled-repos (subscription-manager)**

The `search-disabled-repos` plug-in allows you to temporarily or permanently enable disabled repositories to help resolve dependencies. With this plug-in enabled, when Yum fails to install a package due to failed dependency resolution, it offers to temporarily enable disabled repositories and try again. If the installation succeeds, Yum also offers to enable the used repositories permanently. Note that the plug-in works only with the repositories that are managed by `subscription-manager` and not with custom repositories.

**IMPORTANT**

If `yum` is executed with the --assumeyes or -y option, or if the assumeyes directive is enabled in `/etc/yum.conf`, the plug-in enables disabled repositories, both temporarily and permanently, without prompting for confirmation. This may lead to problems, for example, enabling repositories that you do not want enabled.

To configure the `search-disabled-repos` plug-in, edit the configuration file located in `/etc/yum/pluginconf.d/search-disabled-repos.conf`. For the list of directives you can use in the [main] section, see the table below.

**Table 8.3. Supported search-disabled-repos.conf directives**

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled=value</td>
<td>Allows you to enable or disable the plug-in. The value must be either 1 (enabled), or 0 (disabled). The plug-in is enabled by default.</td>
</tr>
</tbody>
</table>
**notify_only=value**  
Allows you to restrict the behavior of the plug-in to notifications only. The value must be either 1 (notify only without modifying the behavior of Yum), or 0 (modify the behavior of Yum). By default the plug-in only notifies the user.

**ignored_repos=repositories**  
Allows you to specify the repositories that will not be enabled by the plug-in.

### kabi (kabi-yum-plugins)

The kabi plug-in checks whether a driver update package conforms with the official Red Hat **kernel Application Binary Interface** (kABI). With this plug-in enabled, when a user attempts to install a package that uses kernel symbols which are not on a whitelist, a warning message is written to the system log. Additionally, configuring the plug-in to run in enforcing mode prevents such packages from being installed at all.

To configure the kabi plug-in, edit the configuration file located in /etc/yum/pluginconf.d/kabi.conf. A list of directives that can be used in the `[main]` section is shown in the table below.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled=value</td>
<td>Allows you to enable or disable the plug-in. The value must be either 1 (enabled), or 0 (disabled). When installed, the plug-in is enabled by default.</td>
</tr>
<tr>
<td>whitelists=directory</td>
<td>Allows you to specify the directory in which the files with supported kernel symbols are located. By default, the kabi plug-in uses files provided by the kernel-abi-whitelists package (that is, the <code>/usr/lib/modules/kabi-rhel70/</code> directory).</td>
</tr>
<tr>
<td>enforce=value</td>
<td>Allows you to enable or disable enforcing mode. The value must be either 1 (enabled), or 0 (disabled). By default, this option is commented out and the kabi plug-in only displays a warning message.</td>
</tr>
</tbody>
</table>

### product-id (subscription-manager)

The product-id plug-in manages product identity certificates for products installed from the Content Delivery Network. The product-id plug-in is installed by default.

### langpacks (yum-langpacks)

The langpacks plug-in is used to search for locale packages of a selected language for every package that is installed. The langpacks plug-in is installed by default.

### aliases (yum-plugin-aliases)

The aliases plug-in adds the alias command-line option which enables configuring and using aliases for yum commands.
yum-changelog (yum-plugin-changelog)
The yum-changelog plug-in adds the --changelog command-line option that enables viewing package change logs before and after updating.

yum-tmprepo (yum-plugin-tmprepo)
The yum-tmprepo plug-in adds the --tmprepo command-line option that takes the URL of a repository file, downloads and enables it for only one transaction. This plug-in tries to ensure the safe temporary usage of repositories. By default, it does not allow to disable the gpg check.

yum-verify (yum-plugin-verify)
The yum-verify plug-in adds the verify, verify-rpm, and verify-all command-line options for viewing verification data on the system.

yum-versionlock (yum-plugin-versionlock)
The yum-versionlock plug-in excludes other versions of selected packages, which enables protecting packages from being updated by newer versions. With the versionlock command-line option, you can view and edit the list of locked packages.

8.7. ADDITIONAL RESOURCES
For more information on how to manage software packages on Red Hat Enterprise Linux, see the resources listed below.

Installed Documentation
- yum(8) — The manual page for the yum command-line utility provides a complete list of supported options and commands.
- yumdb(8) — The manual page for the yumdb command-line utility documents how to use this tool to query and, if necessary, alter the yum database.
- yum.conf(5) — The manual page named yum.conf documents available yum configuration options.
- yum-utils(1) — The manual page named yum-utils lists and briefly describes additional utilities for managing yum configuration, manipulating repositories, and working with yum database.

Online Resources
- Yum Guides — The Yum Guides page on the project home page provides links to further documentation.
- Red Hat Customer Portal Labs — The Red Hat Customer Portal Labs includes a “Yum Repository Configuration Helper”.

- Appendix A, RPM describes the RPM Package Manager (RPM), the packaging system used by Red Hat Enterprise Linux.
PART IV. INFRASTRUCTURE SERVICES

This part provides information on how to configure services and daemons and enable remote access to a Red Hat Enterprise Linux machine.
CHAPTER 9. MANAGING SERVICES WITH SYSTEMD

9.1. INTRODUCTION TO SYSTEMD

Systemd is a system and service manager for Linux operating systems. It is designed to be backwards compatible with SysV init scripts, and provides a number of features such as parallel startup of system services at boot time, on-demand activation of daemons, or dependency-based service control logic. In Red Hat Enterprise Linux 7, systemd replaces Upstart as the default init system.

Systemd introduces the concept of systemd units. These units are represented by unit configuration files located in one of the directories listed in Table 9.2, “Systemd Unit Files Locations”, and encapsulate information about system services, listening sockets, and other objects that are relevant to the init system. For a complete list of available systemd unit types, see Table 9.1, “Available systemd Unit Types”.

Table 9.1. Available systemd Unit Types

<table>
<thead>
<tr>
<th>Unit Type</th>
<th>File Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service unit</td>
<td>.service</td>
<td>A system service.</td>
</tr>
<tr>
<td>Target unit</td>
<td>.target</td>
<td>A group of systemd units.</td>
</tr>
<tr>
<td>Automount unit</td>
<td>.automount</td>
<td>A file system automount point.</td>
</tr>
<tr>
<td>Device unit</td>
<td>.device</td>
<td>A device file recognized by the kernel.</td>
</tr>
<tr>
<td>Mount unit</td>
<td>.mount</td>
<td>A file system mount point.</td>
</tr>
<tr>
<td>Path unit</td>
<td>.path</td>
<td>A file or directory in a file system.</td>
</tr>
<tr>
<td>Scope unit</td>
<td>.scope</td>
<td>An externally created process.</td>
</tr>
<tr>
<td>Slice unit</td>
<td>.slice</td>
<td>A group of hierarchically organized units that manage system processes.</td>
</tr>
<tr>
<td>Snapshot unit</td>
<td>.snapshot</td>
<td>A saved state of the systemd manager.</td>
</tr>
<tr>
<td>Socket unit</td>
<td>.socket</td>
<td>An inter-process communication socket.</td>
</tr>
<tr>
<td>Swap unit</td>
<td>.swap</td>
<td>A swap device or a swap file.</td>
</tr>
<tr>
<td>Timer unit</td>
<td>.timer</td>
<td>A systemd timer.</td>
</tr>
</tbody>
</table>

<td>/usr/lib/systemd/system/</td>
<td>Systemd unit files distributed with installed RPM packages.</td>
</tr>
</tbody>
</table>
Overriding the Default systemd Configuration Using `system.conf`
The default configuration of systemd is defined during the compilation and it can be found in systemd configuration file at `/etc/systemd/system.conf`. Use this file if you want to deviate from those defaults and override selected default values for systemd units globally.

For example, to override the default value of the timeout limit, which is set to 90 seconds, use the `DefaultTimeoutStartSec` parameter to input the required value in seconds.

```
DefaultTimeoutStartSec=required value
```

See also Example 9.21, “Changing the timeout limit”.

### 9.1.1. Main Features

In Red Hat Enterprise Linux 7, the systemd system and service manager provides the following main features:

- **Socket-based activation** — At boot time, systemd creates listening sockets for all system services that support this type of activation, and passes the sockets to these services as soon as they are started. This not only allows systemd to start services in parallel, but also makes it possible to restart a service without losing any message sent to it while it is unavailable: the corresponding socket remains accessible and all messages are queued.

  Systemd uses **socket units** for socket-based activation.

- **Bus-based activation** — System services that use D-Bus for inter-process communication can be started on-demand the first time a client application attempts to communicate with them. Systemd uses **D-Bus service files** for bus-based activation.

- **Device-based activation** — System services that support device-based activation can be started on-demand when a particular type of hardware is plugged in or becomes available. Systemd uses **device units** for device-based activation.

- **Path-based activation** — System services that support path-based activation can be started on-demand when a particular file or directory changes its state. Systemd uses **path units** for path-based activation.

- **Mount and automount point management**— Systemd monitors and manages mount and automount points. Systemd uses **mount units** for mount points and **autmount units** for automount points.

- **Aggressive parallelization** — Because of the use of socket-based activation, systemd can start system services in parallel as soon as all listening sockets are in place. In combination with system services that support on-demand activation, parallel activation significantly reduces
the time required to boot the system.

- **Transactional unit activation logic**— Before activating or deactivating a unit, systemd calculates its dependencies, creates a temporary transaction, and verifies that this transaction is consistent. If a transaction is inconsistent, systemd automatically attempts to correct it and remove non-essential jobs from it before reporting an error.

- **Backwards compatibility with SysV init**— Systemd supports SysV init scripts as described in the *Linux Standard Base Core Specification* which eases the upgrade path to systemd service units.

### 9.1.2. Compatibility Changes

The systemd system and service manager is designed to be mostly compatible with SysV init and Upstart. The following are the most notable compatibility changes with regards to the previous major release of the Red Hat Enterprise Linux system:

- Systemd has only limited support for runlevels. It provides a number of target units that can be directly mapped to these runlevels and for compatibility reasons, it is also distributed with the earlier `runlevel` command. Not all systemd targets can be directly mapped to runlevels, however, and as a consequence, this command might return `N` to indicate an unknown runlevel. It is recommended that you avoid using the `runlevel` command if possible.

  For more information about systemd targets and their comparison with runlevels, see Section 9.3, “Working with systemd Targets”.

- The `systemctl` utility does not support custom commands. In addition to standard commands such as `start`, `stop`, and `status`, authors of SysV init scripts could implement support for any number of arbitrary commands in order to provide additional functionality. For example, the init script for `iptables` in Red Hat Enterprise Linux 6 could be executed with the `panic` command, which immediately enabled panic mode and reconfigured the system to start dropping all incoming and outgoing packets. This is not supported in systemd and the `systemctl` only accepts documented commands.

  For more information about the `systemctl` utility and its comparison with the earlier `service` utility, see Section 9.2, “Managing System Services”.

- The `systemctl` utility does not communicate with services that have not been started by systemd. When systemd starts a system service, it stores the ID of its main process in order to keep track of it. The `systemctl` utility then uses this PID to query and manage the service. Consequently, if a user starts a particular daemon directly on the command line, `systemctl` is unable to determine its current status or stop it.

- Systemd stops only running services. Previously, when the shutdown sequence was initiated, Red Hat Enterprise Linux 6 and earlier releases of the system used symbolic links located in the `/etc/rc0.d/` directory to stop all available system services regardless of their status. With systemd, only running services are stopped on shutdown.

- System services are unable to read from the standard input stream. When systemd starts a service, it connects its standard input to `/dev/null` to prevent any interaction with the user.

- System services do not inherit any context (such as the `HOME` and `PATH` environment variables) from the invoking user and their session. Each service runs in a clean execution context.

- When loading a SysV init script, systemd reads dependency information encoded in the Linux Standard Base (LSB) header and interprets it at run time.
All operations on service units are subject to a default timeout of 5 minutes to prevent a malfunctioning service from freezing the system. This value is hardcoded for services that are generated from initscripts and cannot be changed. However, individual configuration files can be used to specify a longer timeout value per service, see Example 9.21, “Changing the timeout limit”.

For a detailed list of compatibility changes introduced with systemd, see the Migration Planning Guide for Red Hat Enterprise Linux 7.

9.2. MANAGING SYSTEM SERVICES

NOTE

To expand your expertise, you might also be interested in the Red Hat System Administration II (RH134) training course.

Previous versions of Red Hat Enterprise Linux, which were distributed with SysV init or Upstart, used init scripts located in the `/etc/rc.d/init.d/` directory. These init scripts were typically written in Bash, and allowed the system administrator to control the state of services and daemons in their system. In Red Hat Enterprise Linux 7, these init scripts have been replaced with service units.

Service units end with the `.service` file extension and serve a similar purpose as init scripts. To view, start, stop, restart, enable, or disable system services, use the `systemctl` command as described in Table 9.3, “Comparison of the service Utility with systemctl”, Table 9.4, “Comparison of the chkconfig Utility with systemctl”, and further in this section. The `service` and `chkconfig` commands are still available in the system and work as expected, but are only included for compatibility reasons and should be avoided.

Table 9.3. Comparison of the service Utility with systemctl

<table>
<thead>
<tr>
<th>service</th>
<th>systemctl</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service name start</td>
<td>systemctl start name.service</td>
<td>Starts a service.</td>
</tr>

<td>Checks if a service is enabled.</td>
</tr>
<tr>
<td><code>chkconfig --list</code></td>
<td>Lists all services and checks if they are enabled.</td>
</tr>
<tr>
<td><code>chkconfig --list</code></td>
<td>Lists services that are ordered to start before the specified unit.</td>
</tr>
<tr>
<td><code>chkconfig --list</code></td>
<td>Lists services that are ordered to start after the specified unit.</td>
</tr>
</tbody>
</table>

### Specifying Service Units

For clarity, all command examples in the rest of this section use full unit names with the `.service` file extension, for example:

```
~$]# systemctl stop nfs-server.service
```

However, the file extension can be omitted, in which case the `systemctl` utility assumes the argument is a service unit. The following command is equivalent to the one above:

```
~$]# systemctl stop nfs-server
```

Additionally, some units have alias names. Those names can have shorter names than units, which can be used instead of the actual unit names. To find all aliases that can be used for a particular unit, use:

```
~$]# systemctl show nfs-server.service -p Names
```

### Behavior of systemctl in a chroot Environment

If you change the root directory using the `chroot` command, most `systemctl` commands refuse to perform any action. The reason for this is that the `systemd` process and the user that used the `chroot` command do not have the same view of the filesystem. This happens, for example, when `systemctl` is invoked from a `kickstart` file.

The exception to this are unit file commands such as the `systemctl enable` and `systemctl disable` commands. These commands do not need a running system and do not affect running processes, but they do affect unit files. Therefore, you can run these commands even in `chroot` environment. For example, to enable the `httpd` service on a system under the `/srv/website1/` directory:

```
-``
9.2.1. Listing Services

To list all currently loaded service units, type the following at a shell prompt:

```bash
systemctl list-units --type service
```

For each service unit file, this command displays its full name (UNIT) followed by a note whether the unit file has been loaded (LOAD), its high-level (ACTIVE) and low-level (SUB) unit file activation state, and a short description (DESCRIPTION).

By default, the `systemctl list-units` command displays only active units. If you want to list all loaded units regardless of their state, run this command with the `--all` or `-a` command line option:

```bash
systemctl list-units --type service --all
```

You can also list all available service units to see if they are enabled. To do so, type:

```bash
systemctl list-unit-files --type service
```

For each service unit, this command displays its full name (UNIT FILE) followed by information whether the service unit is enabled or not (STATE). For information on how to determine the status of individual service units, see Section 9.2.2, “Displaying Service Status”.

**Example 9.1. Listing Services**

To list all currently loaded service units, run the following command:

```bash
~]$ systemctl list-units --type service
UNIT                          LOAD   ACTIVE SUB     DESCRIPTION
abrt-ccpp.service             loaded active exited  Install ABRT
coredump hook
abrt-oops.service             loaded active running ABRT kernel log watcher
abrt-vmcore.service           loaded active exited  Harvest vmcores for ABRT
abrt-xorg.service             loaded active running ABRT Xorg log watcher
abrtd.service                 loaded active running ABRT Automated Bug Reporting Tool ...
systemd-vconsole-setup.service loaded active exited  Setup Virtual Console
tog-pegasus.service           loaded active running OpenPegasus CIM Server
```

LOAD = Reflects whether the unit definition was properly loaded.
ACTIVE = The high-level unit activation state, i.e. generalization of SUB.
SUB  = The low-level unit activation state, values depend on unit type.

46 loaded units listed. Pass --all to see loaded but inactive units, too.
To show all installed unit files use 'systemctl list-unit-files'

To list all installed service unit files to determine if they are enabled, type:

- ]$ systemctl list-unit-files --type service

<table>
<thead>
<tr>
<th>UNIT FILE</th>
<th>STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>abrt-ccpp.service</td>
<td>enabled</td>
</tr>
<tr>
<td>abrt-oops.service</td>
<td>enabled</td>
</tr>
<tr>
<td>abrt-vmcore.service</td>
<td>enabled</td>
</tr>
<tr>
<td>abrt-xorg.service</td>
<td>enabled</td>
</tr>
<tr>
<td>abrtd.service</td>
<td>enabled</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>wpa_supplicant.service</td>
<td>disabled</td>
</tr>
<tr>
<td>ypbind.service</td>
<td>disabled</td>
</tr>
</tbody>
</table>

208 unit files listed.

9.2.2. Displaying Service Status

To display detailed information about a service unit that corresponds to a system service, type the following at a shell prompt:

```
$ systemctl status name.service
```

Replace name with the name of the service unit you want to inspect (for example, gdm). This command displays the name of the selected service unit followed by its short description, one or more fields described in Table 9.5, “Available Service Unit Information”, and if it is executed by the root user, also the most recent log entries.

Table 9.5. Available Service Unit Information

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loaded</td>
<td>Information whether the service unit has been loaded, the absolute path to</td>
</tr>
<tr>
<td></td>
<td>the unit file, and a note whether the unit is enabled.</td>
</tr>
<tr>
<td>Active</td>
<td>Information whether the service unit is running followed by a time stamp.</td>
</tr>
<tr>
<td>Main PID</td>
<td>The PID of the corresponding system service followed by its name.</td>
</tr>
<tr>
<td>Status</td>
<td>Additional information about the corresponding system service.</td>
</tr>
<tr>
<td>Process</td>
<td>Additional information about related processes.</td>
</tr>
<tr>
<td>CGroup</td>
<td>Additional information about related Control Groups (cgroups).</td>
</tr>
</tbody>
</table>
To only verify that a particular service unit is running, run the following command:

```
systemctl is-active name.service
```

Similarly, to determine whether a particular service unit is enabled, type:

```
systemctl is-enabled name.service
```

Note that both `systemctl is-active` and `systemctl is-enabled` return an exit status of 0 if the specified service unit is running or enabled. For information on how to list all currently loaded service units, see Section 9.2.1, “Listing Services”.

**Example 9.2. Displaying Service Status**

The service unit for the GNOME Display Manager is named `gdm.service`. To determine the current status of this service unit, type the following at a shell prompt:

```
~# systemctl status gdm.service
```

```
gdm.service - GNOME Display Manager
   Loaded: loaded (/usr/lib/systemd/system/gdm.service; enabled)
   Active: active (running) since Thu 2013-10-17 17:31:23 CEST; 5min ago
   Main PID: 1029 (gdm)
   CGroup: /system.slice/gdm.service
           └─1029 /usr/sbin/gdm
              └─1037 /usr/libexec/gdm-simple-slave --display-id
/or... /r...
```

Oct 17 17:31:23 localhost systemd[1]: Started GNOME Display Manager.

**Example 9.3. Displaying Services Ordered to Start Before a Service**

To determine what services are ordered to start before the specified service, type the following at a shell prompt:

```
~# systemctl list-dependencies --after gdm.service
```

```
gdm.service
└─dbus.socket
└─getty@tty1.service
└─livesys.service
└─plymouth-quit.service
└─system.slice
   └─systemd-journald.socket
   └─systemd-user-sessions.service
      └─basic.target
```

[output truncated]

**Example 9.4. Displaying Services Ordered to Start After a Service**

```
To determine what services are ordered to start after the specified service, type the following at a shell prompt:

```
~]# systemctl list-dependencies --before gdm.service
```

```
gdm.service
  └─dracut-shutdown.service
  └─graphical.target
    └─systemd-readahead-done.service
    └─systemd-readahead-done.timer
    └─systemd-update-utmp-runlevel.service
  └─shutdown.target
    └─systemd-reboot.service
    └─final.target
    └─systemd-reboot.service
```

### 9.2.3. Starting a Service

To start a service unit that corresponds to a system service, type the following at a shell prompt as root:

```
systemctl start name.service
```

Replace `name` with the name of the service unit you want to start (for example, `gdm`). This command starts the selected service unit in the current session. For information on how to enable a service unit to be started at boot time, see Section 9.2.6, “Enabling a Service”. For information on how to determine the status of a certain service unit, see Section 9.2.2, “Displaying Service Status”.

#### Example 9.5. Starting a Service

The service unit for the Apache HTTP Server is named `httpd.service`. To activate this service unit and start the `httpd` daemon in the current session, run the following command as root:

```
~]# systemctl start httpd.service
```

### 9.2.4. Stopping a Service

To stop a service unit that corresponds to a system service, type the following at a shell prompt as root:

```
systemctl stop name.service
```

Replace `name` with the name of the service unit you want to stop (for example, `bluetooth`). This command stops the selected service unit in the current session. For information on how to disable a service unit and prevent it from being started at boot time, see Section 9.2.7, “Disabling a Service”. For information on how to determine the status of a certain service unit, see Section 9.2.2, “Displaying Service Status”.

#### Example 9.6. Stopping a Service
The service unit for the `bluetoothd` daemon is named `bluetooth.service`. To deactivate this service unit and stop the `bluetoothd` daemon in the current session, run the following command as root:

```
[~]# systemctl stop bluetooth.service
```

### 9.2.5. Restarting a Service

To restart a service unit that corresponds to a system service, type the following at a shell prompt as root:

```
systemctl restart name.service
```

Replace `name` with the name of the service unit you want to restart (for example, `httpd`). This command stops the selected service unit in the current session and immediately starts it again. Importantly, if the selected service unit is not running, this command starts it too. To tell systemd to restart a service unit only if the corresponding service is already running, run the following command as root:

```
systemctl try-restart name.service
```

Certain system services also allow you to reload their configuration without interrupting their execution. To do so, type as root:

```
systemctl reload name.service
```

Note that system services that do not support this feature ignore this command altogether. For convenience, the `systemctl` command also supports the `reload-or-restart` and `reload-or-try-restart` commands that restart such services instead. For information on how to determine the status of a certain service unit, see Section 9.2.2, “Displaying Service Status”.

### Example 9.7. Restarting a Service

In order to prevent users from encountering unnecessary error messages or partially rendered web pages, the Apache HTTP Server allows you to edit and reload its configuration without the need to restart it and interrupt actively processed requests. To do so, type the following at a shell prompt as root:

```
[~]# systemctl reload httpd.service
```

### 9.2.6. Enabling a Service

To configure a service unit that corresponds to a system service to be automatically started at boot time, type the following at a shell prompt as root:

```
systemctl enable name.service
```

Replace `name` with the name of the service unit you want to enable (for example, `httpd`). This command reads the `[Install]` section of the selected service unit and creates appropriate symbolic
links to the /usr/lib/systemd/system/name.service file in the /etc/systemd/system/ directory and its subdirectories. This command does not, however, rewrite links that already exist. If you want to ensure that the symbolic links are re-created, use the following command as root:

```systemctl reenable name.service```

This command disables the selected service unit and immediately enables it again. For information on how to determine whether a certain service unit is enabled to start at boot time, see Section 9.2.2, “Displaying Service Status”. For information on how to start a service in the current session, see Section 9.2.3, “Starting a Service”.

**Example 9.8. Enabling a Service**

To configure the Apache HTTP Server to start automatically at boot time, run the following command as root:

```
~# systemctl enable httpd.service
Created symlink from /etc/systemd/system/multi-user.target.wants/httpd.service to /usr/lib/systemd/system/httpd.service.
```

### 9.2.7. Disabling a Service

To prevent a service unit that corresponds to a system service from being automatically started at boot time, type the following at a shell prompt as root:

```systemctl disable name.service```

Replace `name` with the name of the service unit you want to disable (for example, `bluetooth`). This command reads the [Install] section of the selected service unit and removes appropriate symbolic links to the /usr/lib/systemd/system/name.service file from the /etc/systemd/system/ directory and its subdirectories. In addition, you can mask any service unit to prevent it from being started manually or by another service. To do so, run the following command as root:

```systemctl mask name.service```

This command replaces the /etc/systemd/system/name.service file with a symbolic link to /dev/null, rendering the actual unit file inaccessible to systemd. To revert this action and unmask a service unit, type as root:

```systemctl unmask name.service```

For information on how to determine whether a certain service unit is enabled to start at boot time, see Section 9.2.2, “Displaying Service Status”. For information on how to stop a service in the current session, see Section 9.2.4, “Stopping a Service”.

**Example 9.9. Disabling a Service**

Example 9.6, “Stopping a Service” illustrates how to stop the `bluetooth.service` unit in the current session. To prevent this service unit from starting at boot time, type the following at a shell prompt as root:
9.2.8. Starting a Conflicting Service

In `systemd`, positive and negative dependencies between services exist. Starting particular service may require starting one or more other services (positive dependency) or stopping one or more services (negative dependency).

When you attempt to start a new service, `systemd` resolves all dependencies automatically. Note that this is done without explicit notification to the user. If you are already running a service, and you attempt to start another service with a negative dependency, the first service is automatically stopped.

For example, if you are running the `postfix` service, and you try to start the `sendmail` service, `systemd` first automatically stops `postfix`, because these two services are conflicting and cannot run on the same port.

9.3. WORKING WITH SYSTEMD TARGETS

Previous versions of Red Hat Enterprise Linux, which were distributed with SysV init or Upstart, implemented a predefined set of runlevels that represented specific modes of operation. These runlevels were numbered from 0 to 6 and were defined by a selection of system services to be run when a particular runlevel was enabled by the system administrator. In Red Hat Enterprise Linux 7, the concept of runlevels has been replaced with `systemd` targets.

Systemd targets are represented by target units. Target units end with the `.target` file extension and their only purpose is to group together other systemd units through a chain of dependencies. For example, the `graphical.target` unit, which is used to start a graphical session, starts system services such as the GNOME Display Manager (`gdm.service`) or Accounts Service (`accounts-daemon.service`) and also activates the `multi-user.target` unit. Similarly, the `multi-user.target` unit starts other essential system services such as NetworkManager (`NetworkManager.service`) or D-Bus (`dbus.service`) and activates another target unit named `basic.target`.

Red Hat Enterprise Linux 7 is distributed with a number of predefined targets that are more or less similar to the standard set of runlevels from the previous releases of this system. For compatibility reasons, it also provides aliases for these targets that directly map them to SysV runlevels. Table 9.6, “Comparison of SysV Runlevels with systemd Targets” provides a complete list of SysV runlevels and their corresponding systemd targets.

**Table 9.6. Comparison of SysV Runlevels with systemd Targets**

<table>
<thead>
<tr>
<th>Runlevel</th>
<th>Target Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>runlevel0.target</code>,</td>
<td>Shut down and power off</td>
</tr>
<tr>
<td></td>
<td><code>poweroff.target</code></td>
<td>the system.</td>
</tr>
<tr>
<td>1</td>
<td><code>runlevel1.target</code>,</td>
<td>Set up a rescue shell.</td>
</tr>
<tr>
<td></td>
<td><code>rescue.target</code></td>
<td></td>
</tr>
</tbody>
</table>
To view, change, or configure systemd targets, use the `systemctl` utility as described in Table 9.7, “Comparison of SysV init Commands with systemctl” and in the sections below. The `runlevel` and `telinit` commands are still available in the system and work as expected, but are only included for compatibility reasons and should be avoided.

<table>
<thead>
<tr>
<th>Runlevel</th>

</tbody>
</table>

Table 9.7. Comparison of SysV init Commands with systemctl

<table>
<thead>
<tr>
<th>Old Command</th>
<th>New Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>runlevel</td>
<td><code>systemctl list-units --type target</code></td>
<td>Lists currently loaded target units.</td>
</tr>
<tr>
<td>telinit runlevel</td>
<td><code>systemctl isolate name.target</code></td>
<td>Changes the current target.</td>
</tr>
</tbody>
</table>

9.3.1. Viewing the Default Target

To determine which target unit is used by default, run the following command:

```
$ systemctl get-default
```

This command resolves the symbolic link located at `/etc/systemd/system/default.target` and displays the result. For information on how to change the default target, see Section 9.3.3, “Changing the Default Target”. For information on how to list all currently loaded target units, see Section 9.3.2, “Viewing the Current Target”.

Example 9.10. Viewing the Default Target

To display the default target unit, type:

```
$ systemctl get-default
```

graphical.target
9.3.2. Viewing the Current Target

To list all currently loaded target units, type the following command at a shell prompt:

```
系统ctl list-units --type target
```

For each target unit, this command displays its full name (UNIT) followed by a note whether the unit has been loaded (LOAD), its high-level (ACTIVE) and low-level (SUB) unit activation state, and a short description (DESCRIPTION).

By default, the `systemctl list-units` command displays only active units. If you want to list all loaded units regardless of their state, run this command with the `--all` or `-a` command line option:

```
系统ctl list-units --type target --all
```

See Section 9.3.1, “Viewing the Default Target” for information on how to display the default target. For information on how to change the current target, see Section 9.3.4, “Changing the Current Target”.

Example 9.11. Viewing the Current Target

To list all currently loaded target units, run the following command:

```
~]$ systemctl list-units --type target
UNIT                  LOAD   ACTIVE SUB    DESCRIPTION
basic.target          loaded active active Basic System
cryptsetup.target     loaded active active Encrypted Volumes
getty.target          loaded active active Login Prompts
graphical.target      loaded active active Graphical Interface
local-fs-pre.target   loaded active active Local File Systems (Pre)
local-fs.target       loaded active active Local File Systems
multi-user.target     loaded active active Multi-User System
network.target        loaded active active Network
paths.target          loaded active active Paths
remote-fs.target      loaded active active Remote File Systems
sockets.target        loaded active active Sockets
sound.target          loaded active active Sound Card
spice-vdagentd.target loaded active active Agent daemon for Spice guests
swap.target           loaded active active Swap
sysinit.target        loaded active active System Initialization
time-sync.target      loaded active active System Time Synchronized	timers.target        loaded active active Timers
```

LOAD   = Reflects whether the unit definition was properly loaded.
ACTIVE = The high-level unit activation state, i.e. generalization of SUB.
SUB    = The low-level unit activation state, values depend on unit type.

17 loaded units listed. Pass --all to see loaded but inactive units, too.
To show all installed unit files use 'systemctl list-unit-files'.
9.3.3. Changing the Default Target

To configure the system to use a different target unit by default, type the following at a shell prompt as root:

```
systemctl set-default name.target
```

Replace `name` with the name of the target unit you want to use by default (for example, `multi-user`). This command replaces the `/etc/systemd/system/default.target` file with a symbolic link to `/usr/lib/systemd/system/name.target`, where `name` is the name of the target unit you want to use. For information on how to change the current target, see Section 9.3.4, “Changing the Current Target”. For information on how to list all currently loaded target units, see Section 9.3.2, “Viewing the Current Target”.

Example 9.12. Changing the Default Target

To configure the system to use the `multi-user.target` unit by default, run the following command as root:

```
~$# systemctl set-default multi-user.target
rm '/etc/systemd/system/default.target'
ln -s '/usr/lib/systemd/system/multi-user.target'
'/etc/systemd/system/default.target'
```

9.3.4. Changing the Current Target

To change to a different target unit in the current session, type the following at a shell prompt as root:

```
systemctl isolate name.target
```

Replace `name` with the name of the target unit you want to use (for example, `multi-user`). This command starts the target unit named `name` and all dependent units, and immediately stops all others. For information on how to change the default target, see Section 9.3.3, “Changing the Default Target”. For information on how to list all currently loaded target units, see Section 9.3.2, “Viewing the Current Target”.

Example 9.13. Changing the Current Target

To turn off the graphical user interface and change to the `multi-user.target` unit in the current session, run the following command as root:

```
~$# systemctl isolate multi-user.target
```

9.3.5. Changing to Rescue Mode

Rescue mode provides a convenient single-user environment and allows you to repair your system in situations when it is unable to complete a regular booting process. In rescue mode, the system
attempts to mount all local file systems and start some important system services, but it does not activate network interfaces or allow more users to be logged into the system at the same time. In Red Hat Enterprise Linux 7, rescue mode is equivalent to single user mode and requires the root password.

To change the current target and enter rescue mode in the current session, type the following at a shell prompt as root:

```
systemctl rescue
```

This command is similar to `systemctl isolate rescue.target`, but it also sends an informative message to all users that are currently logged into the system. To prevent systemd from sending this message, run this command with the `--no-wall` command line option:

```
systemctl --no-wall rescue
```

For information on how to enter emergency mode, see Section 9.3.6, “Changing to Emergency Mode”.

To enter rescue mode in the current session, run the following command as root:

```
~]$# systemctl rescue
```

Broadcast message from root@localhost on pts/0 (Fri 2013-10-25 18:23:15 CEST):

The system is going down to rescue mode NOW!

**9.3.6. Changing to Emergency Mode**

Emergency mode provides the most minimal environment possible and allows you to repair your system even in situations when the system is unable to enter rescue mode. In emergency mode, the system mounts the root file system only for reading, does not attempt to mount any other local file systems, does not activate network interfaces, and only starts a few essential services. In Red Hat Enterprise Linux 7, emergency mode requires the root password.

To change the current target and enter emergency mode, type the following at a shell prompt as root:

```
systemctl emergency
```

This command is similar to `systemctl isolate emergency.target`, but it also sends an informative message to all users that are currently logged into the system. To prevent systemd from sending this message, run this command with the `--no-wall` command line option:

```
systemctl --no-wall emergency
```

For information on how to enter rescue mode, see Section 9.3.5, “Changing to Rescue Mode”.

**Example 9.15. Changing to Emergency Mode**
To enter emergency mode without sending a message to all users that are currently logged into the system, run the following command as root:

```bash
~]# systemctl --no-wall emergency
```

## 9.4. SHUTTING DOWN, SUSPENDING, AND HIBERNATING THE SYSTEM

In Red Hat Enterprise Linux 7, the `systemctl` utility replaces a number of power management commands used in previous versions of the Red Hat Enterprise Linux system. The commands listed in Table 9.8, “Comparison of Power Management Commands with systemctl” are still available in the system for compatibility reasons, but it is advised that you use `systemctl` when possible.

### Table 9.8. Comparison of Power Management Commands with systemctl

<table>
<thead>
<tr>
<th>Old Command</th>
<th>New Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>halt</td>
<td>systemctl halt</td>
<td>Halts the system.</td>
</tr>
<tr>
<td>poweroff</td>
<td>systemctl poweroff</td>
<td>Powers off the system.</td>
</tr>
<tr>
<td>reboot</td>
<td>systemctl reboot</td>
<td>Restarts the system.</td>
</tr>
<tr>
<td>pm-suspend</td>
<td>systemctl suspend</td>
<td>Suspends the system.</td>
</tr>
<tr>
<td>pm-hibernate</td>
<td>systemctl hibernate</td>
<td>Hibernates the system.</td>
</tr>
<tr>
<td>pm-suspend-hybrid</td>
<td>systemctl hybrid-sleep</td>
<td>Hibernates and suspends the system.</td>
</tr>
</tbody>
</table>

### 9.4.1. Shutting Down the System

The `systemctl` utility provides commands for shutting down the system, however the traditional `shutdown` command is also supported. Although the `shutdown` command will call the `systemctl` utility to perform the shutdown, it has an advantage in that it also supports a time argument. This is particularly useful for scheduled maintenance and to allow more time for users to react to the warning that a system shutdown has been scheduled. The option to cancel the shutdown can also be an advantage.

#### Using systemctl Commands

To shut down the system and power off the machine, type the following at a shell prompt as root:

```bash
systemctl poweroff
```

To shut down and halt the system without powering off the machine, run the following command as root:

```bash
systemctl halt
```
By default, running either of these commands causes systemd to send an informative message to all users that are currently logged into the system. To prevent systemd from sending this message, run the selected command with the \texttt{--no-wall} command line option, for example:

\begin{verbatim}
    systemctl --no-wall poweroff
\end{verbatim}

Using the \texttt{shutdown} Command

To shut down the system and power off the machine at a certain time, use a command in the following format as \texttt{root}:

\begin{verbatim}
    shutdown --poweroff \texttt{hh:mm}
\end{verbatim}

Where \texttt{hh:mm} is the time in 24 hour clock format. The \texttt{/run/nologin} file is created 5 minutes before system shutdown to prevent new logins. When a time argument is used, an optional message, the \textit{wall message}, can be appended to the command.

To shut down and halt the system after a delay, without powering off the machine, use a command in the following format as \texttt{root}:

\begin{verbatim}
    shutdown --halt +m
\end{verbatim}

Where \texttt{+m} is the delay time in minutes. The \texttt{now} keyword is an alias for \texttt{+0}.

A pending shutdown can be canceled by the \texttt{root} user as follows:

\begin{verbatim}
    shutdown -c
\end{verbatim}

See the \texttt{shutdown(8)} manual page for further command options.

9.4.2. Restarting the System

To restart the system, run the following command as \texttt{root}:

\begin{verbatim}
    systemctl reboot
\end{verbatim}

By default, this command causes systemd to send an informative message to all users that are currently logged into the system. To prevent systemd from sending this message, run this command with the \texttt{--no-wall} command line option:

\begin{verbatim}
    systemctl --no-wall reboot
\end{verbatim}

9.4.3. Suspending the System

To suspend the system, type the following at a shell prompt as \texttt{root}:

\begin{verbatim}
    systemctl suspend
\end{verbatim}

This command saves the system state in RAM and with the exception of the RAM module, powers off most of the devices in the machine. When you turn the machine back on, the system then restores its state from RAM without having to boot again. Because the system state is saved in RAM and not on the hard disk, restoring the system from suspend mode is significantly faster than restoring it from hibernation, but as a consequence, a suspended system state is also vulnerable to power outages.
For information on how to hibernate the system, see Section 9.4.4, “Hibernating the System”.

9.4.4. Hibernating the System

To hibernate the system, type the following at a shell prompt as root:

```bash
systemctl hibernate
```

This command saves the system state on the hard disk drive and powers off the machine. When you turn the machine back on, the system then restores its state from the saved data without having to boot again. Because the system state is saved on the hard disk and not in RAM, the machine does not have to maintain electrical power to the RAM module, but as a consequence, restoring the system from hibernation is significantly slower than restoring it from suspend mode.

To hibernate and suspend the system, run the following command as root:

```bash
systemctl hybrid-sleep
```

For information on how to suspend the system, see Section 9.4.3, “Suspending the System”.

9.5. CONTROLLING SYSTEMD ON A REMOTE MACHINE

In addition to controlling the systemd system and service manager locally, the `systemctl` utility also allows you to interact with systemd running on a remote machine over the SSH protocol. Provided that the `sshd` service on the remote machine is running, you can connect to this machine by running the `systemctl` command with the `--host` or `-H` command line option:

```bash
systemctl --host user_name@host_name command
```

Replace `user_name` with the name of the remote user, `host_name` with the machine's host name, and `command` with any of the `systemctl` commands described above. Note that the remote machine must be configured to allow the selected user remote access over the SSH protocol. For more information on how to configure an SSH server, see Chapter 11, OpenSSH.

Example 9.16. Remote Management

To log in to a remote machine named `server-01.example.com` as the root user and determine the current status of the `httpd.service` unit, type the following at a shell prompt:

```bash
~]$ systemctl -H root@server-01.example.com status httpd.service
>>> systemd unit files -- update
root@server-01.example.com's password:
httpd.service - The Apache HTTP Server
  Loaded: loaded (/usr/lib/systemd/system/httpd.service; enabled)
  Active: active (running) since Fri 2013-11-01 13:58:56 CET; 2h 48min ago
  Main PID: 649
  Status: "Total requests: 0; Current requests/sec: 0; Current traffic: 0 B/sec"
  CGroup: /system.slice/httpd.service
```
9.6. CREATING AND MODIFYING SYSTEMD UNIT FILES

A unit file contains configuration directives that describe the unit and define its behavior. Several systemctl commands work with unit files in the background. To make finer adjustments, system administrator must edit or create unit files manually. Table 9.2, “Systemd Unit Files Locations” lists three main directories where unit files are stored on the system, the /etc/systemd/system/ directory is reserved for unit files created or customized by the system administrator.

Unit file names take the following form:

```
unit_name.type_extension
```

Here, `unit_name` stands for the name of the unit and `type_extension` identifies the unit type, see Table 9.1, “Available systemd Unit Types” for a complete list of unit types. For example, there usually is sshd.service as well as sshd.socket unit present on your system.

Unit files can be supplemented with a directory for additional configuration files. For example, to add custom configuration options to sshd.service, create the sshd.service.d/custom.conf file and insert additional directives there. For more information on configuration directories, see Section 9.6.4, “Modifying Existing Unit Files”.

Also, the sshd.service.wants/ and sshd.service.requires/ directories can be created. These directories contain symbolic links to unit files that are dependencies of the sshd service. The symbolic links are automatically created either during installation according to [Install] unit file options (see Table 9.11, “Important [Install] Section Options”) or at runtime based on [Unit] options (see Table 9.9, “Important [Unit] Section Options”). It is also possible to create these directories and symbolic links manually.

Many unit file options can be set using the so called unit specifiers – wildcard strings that are dynamically replaced with unit parameters when the unit file is loaded. This enables creation of generic unit files that serve as templates for generating instantiated units. See Section 9.6.5, “Working with Instantiated Units” for details.

9.6.1. Understanding the Unit File Structure

Unit files typically consist of three sections:

- [Unit] – contains generic options that are not dependent on the type of the unit. These options provide unit description, specify the unit’s behavior, and set dependencies to other units. For a list of most frequently used [Unit] options, see Table 9.9, “Important [Unit] Section Options”.

- [unit type] – if a unit has type-specific directives, these are grouped under a section named after the unit type. For example, service unit files contain the [Service] section, see Table 9.10, “Important [Service] Section Options” for most frequently used [Service] options.

- [Install] – contains information about unit installation used by systemctl enable and disable commands, see Table 9.11, “Important [Install] Section Options” for a list of [Install] options.

**Table 9.9. Important [Unit] Section Options**

<table>
<thead>
<tr>
<th>Option[a]</th>
<th>Description</th>
</tr>
</thead>
</table>

---

118
<table>
<thead>
<tr>
<th>Option[a]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>A meaningful description of the unit. This text is displayed for example in the output of the <code>systemctl status</code> command.</td>
</tr>
<tr>
<td>Documentation</td>
<td>Provides a list of URIs referencing documentation for the unit.</td>
</tr>
<tr>
<td>After[b]</td>
<td>Defines the order in which units are started. The unit starts only after the units specified in <code>After</code> are active. Unlike <code>Requires</code>, <code>After</code> does not explicitly activate the specified units. The <code>Before</code> option has the opposite functionality to <code>After</code>.</td>
</tr>
<tr>
<td>Requires</td>
<td>Configures dependencies on other units. The units listed in <code>Requires</code> are activated together with the unit. If any of the required units fail to start, the unit is not activated.</td>
</tr>
<tr>
<td>Wants</td>
<td>Configures weaker dependencies than <code>Requires</code>. If any of the listed units does not start successfully, it has no impact on the unit activation. This is the recommended way to establish custom unit dependencies.</td>
</tr>
<tr>
<td>Conflicts</td>
<td>Configures negative dependencies, an opposite to <code>Requires</code>.</td>
</tr>
</tbody>
</table>

[a] For a complete list of options configurable in the [Unit] section, see the `systemd.unit(5)` manual page.

[b] In most cases, it is sufficient to set only the ordering dependencies with `After` and `Before` unit file options. If you also set a requirement dependency with `Wants` (recommended) or `Requires`, the ordering dependency still needs to be specified. That is because ordering and requirement dependencies work independently from each other.

Table 9.10. Important [Service] Section Options

<table>
<thead>
<tr>
<th>Option[a]</th>
<th>Description</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Option[a]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Configures the unit process startup type that affects the functionality of <strong>ExecStart</strong> and related options. One of:</td>
</tr>
<tr>
<td></td>
<td>- <strong>simple</strong> – The default value. The process started with <strong>ExecStart</strong> is the main process of the service.</td>
</tr>
<tr>
<td></td>
<td>- <strong>forking</strong> – The process started with <strong>ExecStart</strong> spawns a child process that becomes the main process of the service. The parent process exits when the startup is complete.</td>
</tr>
<tr>
<td></td>
<td>- <strong>oneshot</strong> – This type is similar to <strong>simple</strong>, but the process exits before starting consequent units.</td>
</tr>
<tr>
<td></td>
<td>- <strong>dbus</strong> – This type is similar to <strong>simple</strong>, but consequent units are started only after the main process gains a D-Bus name.</td>
</tr>
<tr>
<td></td>
<td>- <strong>notify</strong> – This type is similar to <strong>simple</strong>, but consequent units are started only after a notification message is sent via the sd_notify() function.</td>
</tr>
<tr>
<td></td>
<td>- <strong>idle</strong> – similar to <strong>simple</strong>, the actual execution of the service binary is delayed until all jobs are finished, which avoids mixing the status output with shell output of services.</td>
</tr>
<tr>
<td><strong>ExecStart</strong></td>
<td>Specifies commands or scripts to be executed when the unit is started. <strong>ExecStartPre</strong> and <strong>ExecStartPost</strong> specify custom commands to be executed before and after <strong>ExecStart</strong>. <strong>Type=oneshot</strong> enables specifying multiple custom commands that are then executed sequentially.</td>
</tr>
<tr>
<td><strong>ExecStop</strong></td>
<td>Specifies commands or scripts to be executed when the unit is stopped.</td>
</tr>
<tr>
<td><strong>ExecReload</strong></td>
<td>Specifies commands or scripts to be executed when the unit is reloaded.</td>
</tr>
<tr>
<td><strong>Restart</strong></td>
<td>With this option enabled, the service is restarted after its process exits, with the exception of a clean stop by the <strong>systemctl</strong> command.</td>
</tr>
<tr>
<td><strong>RemainAfterExit</strong></td>
<td>If set to True, the service is considered active even when all its processes exited. Default value is False. This option is especially useful if <strong>Type=oneshot</strong> is configured.</td>
</tr>
</tbody>
</table>

[a] For a complete list of options configurable in the [Service] section, see the **systemd.service(5)** manual page.

Table 9.11. Important [Install] Section Options

<table>
<thead>
<tr>
<th>Option[a]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alias</strong></td>
<td>Provides a space-separated list of additional names for the unit. Most <strong>systemctl</strong> commands, excluding <strong>systemctl enable</strong>, can use aliases instead of the actual unit name.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RequiredBy</td>
<td>A list of units that depend on the unit. When this unit is enabled, the units listed in RequiredBy gain a Require dependency on the unit.</td>
</tr>
<tr>
<td>WantedBy</td>
<td>A list of units that weakly depend on the unit. When this unit is enabled, the units listed in WantedBy gain a Want dependency on the unit.</td>
</tr>
<tr>
<td>Also</td>
<td>Specifies a list of units to be installed or uninstalled along with the unit.</td>
</tr>
<tr>
<td>DefaultInstance</td>
<td>Limited to instantiated units, this option specifies the default instance for which the unit is enabled. See Section 9.6.5, “Working with Instantiated Units”</td>
</tr>
</tbody>
</table>

[a] For a complete list of options configurable in the [Install] section, see the systemd.unit(5) manual page.

A whole range of options that can be used to fine tune the unit configuration, Example 9.17, “postfix.service Unit File” shows an example of a service unit installed on the system. Moreover, unit file options can be defined in a way that enables dynamic creation of units as described in Section 9.6.5, “Working with Instantiated Units”.

**Example 9.17. postfix.service Unit File**

What follows is the content of the /usr/lib/systemd/system/postfix.service unit file as currently provided by the postfix package:

```ini
[Unit]
Description=Postfix Mail Transport Agent
After=syslog.target network.target
Conflicts=sendmail.service exim.service

[Service]
Type=forking
PIDFile=/var/spool/postfix/pid/master.pid
EnvironmentFile=-/etc/sysconfig/network
ExecStartPre=-/usr/libexec/postfix/aliasesdb
ExecStartPre=-/usr/libexec/postfix/chroot-update
ExecStart=/usr/sbin/postfix start
ExecReload=/usr/sbin/postfix reload
ExecStop=/usr/sbin/postfix stop

[Install]
WantedBy=multi-user.target
```

The [Unit] section describes the service, specifies the ordering dependencies, as well as conflicting units. In [Service], a sequence of custom scripts is specified to be executed during unit activation, on stop, and on reload. EnvironmentFile points to the location where environment variables for the service are defined, PIDFile specifies a stable PID for the main process of the service. Finally, the [Install] section lists units that depend on the service.
9.6.2. Creating Custom Unit Files

There are several use cases for creating unit files from scratch: you could run a custom daemon, create a second instance of some existing service (as in Example 9.19, “Creating a second instance of the sshd service”), or import a SysV init script (more in Section 9.6.3, “Converting SysV Init Scripts to Unit Files”). On the other hand, if you intend just to modify or extend the behavior of an existing unit, use the instructions from Section 9.6.4, “Modifying Existing Unit Files”. The following procedure describes the general process of creating a custom service:

1. Prepare the executable file with the custom service. This can be a custom-created script, or an executable delivered by a software provider. If required, prepare a PID file to hold a constant PID for the main process of the custom service. It is also possible to include environment files to store shell variables for the service. Make sure the source script is executable (by executing the `chmod a+x`) and is not interactive.

2. Create a unit file in the `/etc/systemd/system/` directory and make sure it has correct file permissions. Execute as root:

   ```
touch /etc/systemd/system/name.service
chmod 664 /etc/systemd/system/name.service
   ```

   Replace `name` with a name of the service to be created. Note that file does not need to be executable.

3. Open the `name.service` file created in the previous step, and add the service configuration options. There is a variety of options that can be used depending on the type of service you wish to create, see Section 9.6.1, “Understanding the Unit File Structure”. The following is an example unit configuration for a network-related service:

   ```
[Unit]
Description=service_description
After=network.target

[Service]
ExecStart=path_to_executable
Type=forking
PIDFile=path_to_pidfile

[Install]
WantedBy=default.target
   ```

Where:

- `service_description` is an informative description that is displayed in journal log files and in the output of the `systemctl status` command.
- the `After` setting ensures that the service is started only after the network is running. Add a space-separated list of other relevant services or targets.
- `path_to_executable` stands for the path to the actual service executable.
- `Type=forking` is used for daemons that make the `fork` system call. The main process of the service is created with the PID specified in `path_to_pidfile`. Find other startup types in Table 9.10, “Important [Service] Section Options”.
- `WantedBy` states the target or targets that the service should be started under. Think of
these targets as of a replacement of the older concept of runlevels, see Section 9.3, “Working with systemd Targets” for details.

4. Notify systemd that a new `name.service` file exists by executing the following command as root:

```shell
systemctl daemon-reload
systemctl start name.service
```

**WARNING**

Always run the `systemctl daemon-reload` command after creating new unit files or modifying existing unit files. Otherwise, the `systemctl start` or `systemctl enable` commands could fail due to a mismatch between states of systemd and actual service unit files on disk.

The `name.service` unit can now be managed as any other system service with commands described in Section 9.2, “Managing System Services”.

**Example 9.18. Creating the emacs.service File**

When using the Emacs text editor, it is often faster and more convenient to have it running in the background instead of starting a new instance of the program whenever editing a file. The following steps show how to create a unit file for Emacs, so that it can be handled like a service.

1. Create a unit file in the `/etc/systemd/system/` directory and make sure it has the correct file permissions. Execute as root:

   ```bash
   ~
   touch /etc/systemd/system/emacs.service
   chmod 664 /etc/systemd/system/emacs.service
   ```

2. Add the following content to the file:

   ```ini
   [Unit]
   Description=Emacs: the extensible, self-documenting text editor

   [Service]
   Type=forking
   ExecStart=/usr/bin/emacs --daemon
   ExecStop=/usr/bin/emacsclient --eval "(kill-emacs)"
   Environment=SSH_AUTH_SOCK=%t/keyring/ssh
   Restart=always

   [Install]
   WantedBy=default.target
   ```

With the above configuration, the `/usr/bin/emacs` executable is started in daemon mode on service start. The `SSH_AUTH.SOCK` environment variable is set using the "%t" unit specifier that stands for the runtime directory. The service also restarts the emacs process.
if it exits unexpectedly.

3. Execute the following commands to reload the configuration and start the custom service:

```
~]# systemctl daemon-reload
~]# systemctl start emacs.service
```

As the editor is now registered as a systemd service, you can use all standard `systemctl` commands. For example, run `systemctl status emacs` to display the editor's status or `systemctl enable emacs` to make the editor start automatically on system boot.

**Example 9.19. Creating a second instance of the sshd service**

System Administrators often need to configure and run multiple instances of a service. This is done by creating copies of the original service configuration files and modifying certain parameters to avoid conflicts with the primary instance of the service. The following procedure shows how to create a second instance of the `sshd` service:

1. Create a copy of the `sshd_config` file that will be used by the second daemon:

```
~]# cp /etc/ssh/sshd{,-second}_config
```

2. Edit the `sshd-second_config` file created in the previous step to assign a different port number and PID file to the second daemon:

```
Port 22220
PidFile /var/run/sshd-second.pid
```

See the `sshd_config(5)` manual page for more information on `Port` and `PidFile` options. Make sure the port you choose is not in use by any other service. The PID file does not have to exist before running the service, it is generated automatically on service start.

3. Create a copy of the systemd unit file for the `sshd` service:

```
~]# cp /usr/lib/systemd/system/sshd.service /etc/systemd/system/sshd-second.service
```

4. Alter the `sshd-second.service` created in the previous step as follows:

   a. Modify the `Description` option:

```
Description=OpenSSH server second instance daemon
```

   b. Add `sshd.service` to services specified in the `After` option, so that the second instance starts only after the first one has already started:

```
After=syslog.target network.target auditd.service sshd.service
```

   c. The first instance of `sshd` includes key generation, therefore remove the `ExecStartPre=/usr/sbin/sshd-keygen` line.
d. Add the `-f /etc/ssh/sshd-second_config` parameter to the `sshd` command, so that the alternative configuration file is used:

```
ExecStart=/usr/sbin/sshd -D -f /etc/ssh/sshd-second_config $OPTIONS
```

e. After the above modifications, the `sshd-second.service` should look as follows:

```
[Unit]
Description=OpenSSH server second instance daemon
After=syslog.target network.target auditd.service sshd.service

[Service]
EnvironmentFile=/etc/sysconfig/sshd
ExecStart=/usr/sbin/sshd -D -f /etc/ssh/sshd-second_config $OPTIONS
ExecReload=/bin/kill -HUP $MAINPID
KillMode=process
Restart=on-failure
RestartSec=42s

[Install]
WantedBy=multi-user.target
```

5. If using SELinux, add the port for the second instance of sshd to SSH ports, otherwise the second instance of sshd will be rejected to bind to the port:

```
~$# semanage port -a -t ssh_port_t -p tcp 22220
```

6. Enable `sshd-second.service`, so that it starts automatically upon boot:

```
~$# systemctl enable sshd-second.service
```

Verify if the `sshd-second.service` is running by using the `systemctl status` command. Also, verify if the port is enabled correctly by connecting to the service:

```
~$# ssh -p 22220 user@server
```

If the firewall is in use, please make sure that it is configured appropriately in order to allow connections to the second instance of sshd.

To learn how to properly choose a target for ordering and dependencies of your custom unit files, see the following articles:

- [How to write a service unit file which enforces that particular services have to be started](#)
- [How to decide what dependencies a systemd service unit definition should have](#)

Additional information with some real-world examples of cases triggered by the ordering and dependencies in a unit file is available in the following article: [Is there any useful information about writing unit files?](#)

If you want to set limits for services started by `systemd`, see the Red Hat Knowledgebase article [How](#)
to set limits for services in RHEL 7 and systemd. These limits need to be set in the service's unit file. Note that systemd ignores limits set in the `/etc/security/limits.conf` and `/etc/security/limits.d/*` configuration files. The limits defined in these files are set by PAM when starting a login session, but daemons started by systemd do not use PAM login sessions.

### 9.6.3. Converting SysV Init Scripts to Unit Files

Before taking time to convert a SysV init script to a unit file, make sure that the conversion was not already done elsewhere. All core services installed on Red Hat Enterprise Linux 7 come with default unit files, and the same applies for many third-party software packages.

Converting an init script to a unit file requires analyzing the script and extracting the necessary information from it. Based on this data you can create a unit file as described in Section 9.6.2, “Creating Custom Unit Files”. As init scripts can vary greatly depending on the type of the service, you might need to employ more configuration options for translation than outlined in this chapter. Note that some levels of customization that were available with init scripts are no longer supported by systemd units, see Section 9.1.2, “Compatibility Changes”.

The majority of information needed for conversion is provided in the script's header. The following example shows the opening section of the init script used to start the `postfix` service on Red Hat Enterprise Linux 6:

```bash
#!/bin/bash
#
# postfix      Postfix Mail Transfer Agent
#
# chkconfig: 2345 80 30
# description: Postfix is a Mail Transport Agent, which is the program \ #              that moves mail from one machine to another.
# processname: master
# pidfile: /var/spool/postfix/pid/master.pid
# config: /etc/postfix/main.cf
# config: /etc/postfix/master.cf

### BEGIN INIT INFO
# Provides: postfix MTA
# Required-Start: $local_fs $network $remote_fs
# Required-Stop: $local_fs $network $remote_fs
# Default-Start: 2 3 4 5
# Default-Stop: 0 1 6
# Short-Description: start and stop postfix
# Description: Postfix is a Mail Transport Agent, which is the program that
#               moves mail from one machine to another.
### END INIT INFO
```

In the above example, only lines starting with `# chkconfig` and `# description` are mandatory, so you might not find the rest in different init files. The text enclosed between the `### BEGIN INIT INFO` and `### END INIT INFO` lines is called Linux Standard Base (LSB) header. If specified, LSB headers contain directives defining the service description, dependencies, and default runlevels. What follows is an overview of analytic tasks aiming to collect the data needed for a new unit file. The postfix init script is used as an example, see the resulting postfix unit file in Example 9.17, “postfix.service Unit File”.

**Finding the Service Description**
Find descriptive information about the script on the line starting with `#description`. Use this description together with the service name in the `Description` option in the `[Unit]` section of the unit file. The LSB header might contain similar data on the `#Short-Description` and `#Description` lines.

**Finding Service Dependencies**
The LSB header might contain several directives that form dependencies between services. Most of them are translatable to systemd unit options, see Table 9.12, “Dependency Options from the LSB Header”

**Table 9.12. Dependency Options from the LSB Header**

<table>
<thead>
<tr>
<th>LSB Option</th>
<th>Description</th>
<th>Unit File Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provides</td>
<td>Specifies the boot facility name of the service, that can be referenced in other init scripts (with the “$” prefix). This is no longer needed as unit files refer to other units by their file names.</td>
<td>–</td>
</tr>
<tr>
<td>Required-Start</td>
<td>Contains boot facility names of required services. This is translated as an ordering dependency, boot facility names are replaced with unit file names of corresponding services or targets they belong to. For example, in case of <code>postfix</code>, the Required-Start dependency on <code>$network</code> was translated to the After dependency on <code>network.target</code>.</td>
<td>After, Before</td>
</tr>
<tr>
<td>Should-Start</td>
<td>Constitutes weaker dependencies than Required-Start. Failed Should-Start dependencies do not affect the service startup.</td>
<td>After, Before</td>
</tr>
<tr>
<td>Required-Stop, Should-Stop</td>
<td>Constitute negative dependencies.</td>
<td>Conflicts</td>
</tr>
</tbody>
</table>

**Finding Default Targets of the Service**
The line starting with `#chkconfig` contains three numerical values. The most important is the first number that represents the default runlevels in which the service is started. Use Table 9.6, “Comparison of SysV Runlevels with systemd Targets” to map these runlevels to equivalent systemd targets. Then list these targets in the `WantedBy` option in the `[Install]` section of the unit file. For example, `postfix` was previously started in runlevels 2, 3, 4, and 5, which translates to `multiuser.target` and `graphical.target` on Red Hat Enterprise Linux 7. Note that the `graphical.target` depends on `multiuser.target`, therefore it is not necessary to specify both, as in Example 9.17, “`postfix.service Unit File`”. You might find information on default and forbidden runlevels also at `#Default-Start` and `#Default-Stop` lines in the LSB header.

The other two values specified on the `#chkconfig` line represent startup and shutdown priorities of the init script. These values are interpreted by systemd if it loads the init script, but there is no unit file equivalent.

**Finding Files Used by the Service**
Init scripts require loading a function library from a dedicated directory and allow importing configuration, environment, and PID files. Environment variables are specified on the line starting with `#config` in the init script header, which translates to the `EnvironmentFile` unit file option. The PID file specified on the `#pidfile` init script line is imported to the unit file with the `PIDFile` option.
The key information that is not included in the init script header is the path to the service executable, and potentially some other files required by the service. In previous versions of Red Hat Enterprise Linux, init scripts used a Bash case statement to define the behavior of the service on default actions, such as `start`, `stop`, or `restart`, as well as custom-defined actions. The following excerpt from the `postfix` init script shows the block of code to be executed at service start.

```
conf_check() {
    [ -x /usr/sbin/postfix ] || exit 5
    [ -d /etc/postfix ] || exit 6
    [ -d /var/spool/postfix ] || exit 5
}
make_aliasesdb() {
    if [ " $(/usr/sbin/postconf -h alias_database)" == "hash:/etc/aliases" ]
    then
        # /etc/aliases.db might be used by other MTA, make sure nothing
        # has touched it since our last newaliases call
        [ /etc/aliases -nt /etc/aliases.db ] ||
        [ "$ALIASESDB_STAMP" -nt /etc/aliases.db ] ||
        [ "$ALIASESDB_STAMP" -ot /etc/aliases.db ] || return
        /usr/bin/newaliases
        touch -r /etc/aliases.db "$ALIASESDB_STAMP"
    else
        /usr/bin/newaliases
    fi
}
start() {
    [ "$EUID" != "0" ] && exit 4
    # Check that networking is up.
    [ ${NETWORKING} = "no" ] && exit 1
    conf_check
    # Start daemons.
    echo -n "$Starting postfix: 
    make_aliasesdb >/dev/null 2>&1
    [ -x $CHROOT_UPDATE ] && $CHROOT_UPDATE
    /usr/sbin/postfix start 2>/dev/null 1>&2 && success || failure "$prog
    start"
    RETVAL=$?
    [ $RETVAL -eq 0 ] && touch $lockfile
    echo
    return $RETVAL
}
```

The extensibility of the init script allowed specifying two custom functions, `conf_check()` and `make_aliasesdb()`, that are called from the `start()` function block. On closer look, several external files and directories are mentioned in the above code: the main service executable `/usr/sbin/postfix`, the `/etc/postfix/` and `/var/spool/postfix/` configuration directories, as well as the `/usr/sbin/postconf/` directory.

Systemd supports only the predefined actions, but enables executing custom executables with `ExecStart`, `ExecStartPre`, `ExecStartPost`, `ExecStop`, and `ExecReload` options. In case of `postfix` on Red Hat Enterprise Linux 7, the `/usr/sbin/postfix` together with supporting scripts are executed on service start. Consult the `postfix` unit file at Example 9.17, “postfix.service Unit File”.

128
Converting complex init scripts requires understanding the purpose of every statement in the script. Some of the statements are specific to the operating system version, therefore you do not need to translate them. On the other hand, some adjustments might be needed in the new environment, both in unit file as well as in the service executable and supporting files.

9.6.4. Modifying Existing Unit Files

Services installed on the system come with default unit files that are stored in the `/usr/lib/systemd/system/` directory. System Administrators should not modify these files directly, therefore any customization must be confined to configuration files in the `/etc/systemd/system/` directory. Depending on the extent of the required changes, pick one of the following approaches:

- Create a directory for supplementary configuration files at `/etc/systemd/system/unit.d/`. This method is recommended for most use cases. It enables extending the default configuration with additional functionality, while still referring to the original unit file. Changes to the default unit introduced with a package upgrade are therefore applied automatically. See the section called “Extending the Default Unit Configuration” for more information.

- Create a copy of the original unit file `/usr/lib/systemd/system/` in `/etc/systemd/system/` and make changes there. The copy overrides the original file, therefore changes introduced with the package update are not applied. This method is useful for making significant unit changes that should persist regardless of package updates. See the section called “Overriding the Default Unit Configuration” for details.

In order to return to the default configuration of the unit, just delete custom-created configuration files in `/etc/systemd/system/`. To apply changes to unit files without rebooting the system, execute:

```
systemctl daemon-reload
```

The `daemon-reload` option reloads all unit files and recreates the entire dependency tree, which is needed to immediately apply any change to a unit file. As an alternative, you can achieve the same result with the following command:

```
init q
```

Also, if the modified unit file belongs to a running service, this service must be restarted to accept new settings:

```
systemctl restart name.service
```
IMPORTANT

To modify properties, such as dependencies or timeouts, of a service that is handled by a
SysV init script, do not modify the init script itself. Instead, create a systemd drop-in
configuration file for the service as described in the section called “Extending the
Default Unit Configuration” and the section called “Overriding the Default Unit
Configuration”. Then manage this service in the same way as a normal systemd service.

For example, to extend the configuration of the network service, do not modify the
/etc/rc.d/init.d/network init script file. Instead, create new directory
/etc/systemd/system/network.service.d/ and a systemd drop-in file
/etc/systemd/system/network.service.d/my_config.conf. Then, put the
modified values into the drop-in file. Note: systemd knows the network service as
network.service, which is why the created directory must be called
network.service.d

Extending the Default Unit Configuration

To extend the default unit file with additional configuration options, first create a configuration
directory in /etc/systemd/system/. If extending a service unit, execute the following command as
root:

```bash
mkdir /etc/systemd/system/name.service.d/
```

Replace name with the name of the service you want to extend. The above syntax applies to all unit
types.

Create a configuration file in the directory made in the previous step. Note that the file name must end
with the .conf suffix. Type:

```bash
touch /etc/systemd/system/name.service.d/config_name.conf
```

Replace config_name with the name of the configuration file. This file adheres to the normal unit file
structure, therefore all directives must be specified under appropriate sections, see Section 9.6.1,
“Understanding the Unit File Structure”.

For example, to add a custom dependency, create a configuration file with the following content:

```ini
[Unit]
Requires=new_dependency
After=new_dependency
```

Where new_dependency stands for the unit to be marked as a dependency. Another example is a
configuration file that restarts the service after its main process exited, with a delay of 30 seconds:

```ini
[Service]
Restart=always
RestartSec=30
```

It is recommended to create small configuration files focused only on one task. Such files can be easily
moved or linked to configuration directories of other services.

To apply changes made to the unit, execute as root:
systemctl daemon-reload
systemctl restart name.service

Example 9.20. Extending the httpd.service Configuration

To modify the httpd.service unit so that a custom shell script is automatically executed when starting the Apache service, perform the following steps. First, create a directory and a custom configuration file:

```
~]$ mkdir /etc/systemd/system/httpd.service.d/
~]$ touch /etc/systemd/system/httpd.service.d/custom_script.conf
```

Provided that the script you want to start automatically with Apache is located at /usr/local/bin/custom.sh, insert the following text to the custom_script.conf file:

```
[Service]
ExecStartPost=/usr/local/bin/custom.sh
```

To apply the unit changes, execute:

```
~]$ systemctl daemon-reload
~]$ systemctl restart httpd.service
```

**NOTE**

The configuration files from configuration directories in /etc/systemd/system/ take precedence over unit files in /usr/lib/systemd/system/. Therefore, if the configuration files contain an option that can be specified only once, such as Description or ExecStart, the default value of this option is overridden. Note that in the output of the systemd-delta command, described in the section called “Monitoring Overriden Units”, such units are always marked as [EXTENDED], even though in sum, certain options are actually overridden.

Overriding the Default Unit Configuration

To make changes that will persist after updating the package that provides the unit file, first copy the file to the /etc/systemd/system/ directory. To do so, execute the following command as root:

```
cp /usr/lib/systemd/system/name.service /etc/systemd/system/name.service
```

Where name stands for the name of the service unit you wish to modify. The above syntax applies to all unit types.

Open the copied file with a text editor, and make the desired changes. To apply the unit changes, execute as root:

```
systemctl daemon-reload
systemctl restart name.service
```

Example 9.21. Changing the timeout limit
You can specify a timeout value per service to prevent a malfunctioning service from freezing the system. Otherwise, timeout is set by default to 90 seconds for normal services and to 300 seconds for SysV-compatible services.

For example, to extend timeout limit for the `httpd` service:

1. Copy the `httpd` unit file to the `/etc/systemd/system/` directory:
   ```bash
cp /usr/lib/systemd/system/httpd.service /etc/systemd/system/httpd.service
   ```

2. Open file `/etc/systemd/system/httpd.service` and specify the `TimeoutStartUSec` value in the `[Service]` section:
   ```
   ... 
   [Service] 
   ... 
   PrivateTmp=true 
   TimeoutStartSec=10 
   
   [Install] 
   WantedBy=multi-user.target 
   ...
   ```

3. Reload the `systemd` daemon:
   ```bash
   systemctl daemon-reload
   ```

4. Optional. Verify the new timeout value:
   ```bash
   systemctl show httpd -p TimeoutStartUSec
   ```

**NOTE**

To change the timeout limit globally, input the `DefaultTimeoutStartSec` in the `/etc/systemd/system.conf` file. See `Section 9.1, “Introduction to systemd”`.

### Monitoring Overridden Units

To display an overview of overridden or modified unit files, use the following command:

```bash
systemd-delta
```

For example, the output of the above command can look as follows:

```
[EQUIVALENT] /etc/systemd/system/default.target → 
/usr/lib/systemd/system/default.target 
[OVERRIDE] /etc/systemd/system/autofs.service → 
/usr/lib/systemd/system/autofs.service 
```
+++ /etc/systemd/system/autofs.service 2014-11-21 10:00:58.513568275 -0500
@@ -8,7 +8,8 @@
    EnvironmentFile=-/etc/sysconfig/autofs
    ExecStart=/usr/sbin/automount $OPTIONS --pid-file /run/autofs.pid
    ExecReload=/usr/bin/kill -HUP $MAINPID
-    TimeoutSec=180
+    TimeoutSec=240
+    Restart=Always

    [Install]
    WantedBy=multi-user.target

    [MASKED] /etc/systemd/system/cups.service →
    /usr/lib/systemd/system/cups.service
    [EXTENDED] /usr/lib/systemd/system/sssd.service →
    /etc/systemd/system/sssd.service.d/journal.conf

4 overridden configuration files found.

Table 9.13, “systemd-delta Difference Types” lists override types that can appear in the output of systemd-delta. Note that if a file is overridden, systemd-delta by default displays a summary of changes similar to the output of the diff command.

Table 9.13. systemd-delta Difference Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[MASKED]</td>
<td>Masked unit files, see Section 9.2.7, “Disabling a Service” for description of unit masking.</td>
</tr>
<tr>
<td>[EQUIVALENT]</td>
<td>Unmodified copies that override the original files but do not differ in content, typically symbolic links.</td>
</tr>
<tr>
<td>[REDIRECTED]</td>
<td>Files that are redirected to another file.</td>
</tr>
<tr>
<td>[OVERRIDEN]</td>
<td>Overridden and changed files.</td>
</tr>
<tr>
<td>[EXTENDED]</td>
<td>Files that are extended with .conf files in the /etc/systemd/system/unit.d/ directory.</td>
</tr>
<tr>
<td>[UNCHANGED]</td>
<td>Unmodified files are displayed only when the --type=unchanged option is used.</td>
</tr>
</tbody>
</table>

It is good practice to run systemd-delta after system update to check if there are any updates to the default units that are currently overridden by custom configuration. It is also possible to limit the output only to a certain difference type. For example, to view just the overridden units, execute:

```
systemd-delta --type=overridden
```

9.6.5. Working with Instantiated Units

It is possible to instantiate multiple units from a single template configuration file at runtime. The "@" character is used to mark the template and to associate units with it. Instantiated units can be started
from another unit file (using Requires or Wants options), or with the systemctl start command. Instantiated service units are named the following way:

```
template_name@instance_name.service
```

Where template_name stands for the name of the template configuration file. Replace instance_name with the name for the unit instance. Several instances can point to the same template file with configuration options common for all instances of the unit. Template unit name has the form of:

```
unit_name@.service
```

For example, the following Wants setting in a unit file:

```
Wants=getty@ttyA.service,getty@ttyB.service
```

first makes systemd search for given service units. If no such units are found, the part between "@" and the type suffix is ignored and systemd searches for the getty@.service file, reads the configuration from it, and starts the services.

Wildcard characters, called unit specifiers, can be used in any unit configuration file. Unit specifiers substitute certain unit parameters and are interpreted at runtime. Table 9.14, “Important Unit Specifiers” lists unit specifiers that are particularly useful for template units.

### Table 9.14. Important Unit Specifiers

<table>
<thead>
<tr>
<th>Unit Specifier</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%n</td>
<td>Full unit name</td>
<td>Stands for the full unit name including the type suffix. %N has the same meaning but also replaces the forbidden characters with ASCII codes.</td>
</tr>
<tr>
<td>%p</td>
<td>Prefix name</td>
<td>Stands for a unit name with type suffix removed. For instantiated units %p stands for the part of the unit name before the &quot;@&quot; character.</td>
</tr>
<tr>
<td>%i</td>
<td>Instance name</td>
<td>Is the part of the instantiated unit name between the &quot;@&quot; character and the type suffix. %I has the same meaning but also replaces the forbidden characters for ASCII codes.</td>
</tr>
<tr>
<td>%H</td>
<td>Host name</td>
<td>Stands for the hostname of the running system at the point in time the unit configuration is loaded.</td>
</tr>
<tr>
<td>%t</td>
<td>Runtime directory</td>
<td>Represents the runtime directory, which is either /run for the root user, or the value of the XDG_RUNTIME_DIR variable for unprivileged users.</td>
</tr>
</tbody>
</table>

For a complete list of unit specifiers, see the systemd.unit(5) manual page.

For example, the getty@.service template contains the following directives:

```
[Unit]
Description=Getty on %i
```
When the getty@ttyA.service and getty@ttyB.service are instantiated from the above template, 
Description= is resolved as Getty on ttyA and Getty on ttyB.

9.7. ADDITIONAL RESOURCES

For more information on systemd and its usage on Red Hat Enterprise Linux 7, see the resources listed below.

Installed Documentation

- systemctl(1) – The manual page for the systemctl command line utility provides a complete list of supported options and commands.
- systemd(1) – The manual page for the systemd system and service manager provides more information about its concepts and documents available command line options and environment variables, supported configuration files and directories, recognized signals, and available kernel options.
- systemd-delta(1) – The manual page for the systemd-delta utility that allows to find extended and overridden configuration files.
- systemd.unit(5) – The manual page named systemd.unit provides detailed information about systemd unit files and documents all available configuration options.
- systemd.service(5) – The manual page named systemd.service documents the format of service unit files.
- systemd.target(5) – The manual page named systemd.target documents the format of target unit files.
- systemd.kill(5) – The manual page named systemd.kill documents the configuration of the process killing procedure.

Online Documentation

- Red Hat Enterprise Linux 7 Networking Guide – The Networking Guide for Red Hat Enterprise Linux 7 documents relevant information regarding the configuration and administration of network interfaces, networks, and network services in this system. It provides an introduction to the hostnamectl utility, explains how to use it to view and set host names on the command line, both locally and remotely, and provides important information about the selection of host names and domain names.
- Red Hat Enterprise Linux 7 Desktop Migration and Administration Guide – The Desktop Migration and Administration Guide for Red Hat Enterprise Linux 7 documents the migration planning, deployment, configuration, and administration of the GNOME 3 desktop on this system. It introduces the logind service, enumerates its most significant features, and explains how to use the loginctl utility to list active sessions and enable multi-seat support.
- Red Hat Enterprise Linux 7 SELinux User’s and Administrator’s Guide – The SELinux User’s and Administrator’s Guide for Red Hat Enterprise Linux 7 describes the basic principles of SELinux and documents in detail how to configure and use SELinux with various services such as the
Apache HTTP Server, Postfix, PostgreSQL, or OpenShift. It explains how to configure SELinux access permissions for system services managed by systemd.

- **Red Hat Enterprise Linux 7 Installation Guide** — The *Installation Guide* for Red Hat Enterprise Linux 7 documents how to install the system on AMD64 and Intel 64 systems, 64-bit IBM Power Systems servers, and IBM System z. It also covers advanced installation methods such as Kickstart installations, PXE installations, and installations over the VNC protocol. In addition, it describes common post-installation tasks and explains how to troubleshoot installation problems, including detailed instructions on how to boot into rescue mode or recover the root password.

- **Red Hat Enterprise Linux 7 Security Guide** — The *Security Guide* for Red Hat Enterprise Linux 7 assists users and administrators in learning the processes and practices of securing their workstations and servers against local and remote intrusion, exploitation, and malicious activity. It also explains how to secure critical system services.

- **systemd Home Page** — The project home page provides more information about systemd.

**See Also**

- **Chapter 1, System Locale and Keyboard Configuration** documents how to manage the system locale and keyboard layouts. It explains how to use the `localectl` utility to view the current locale, list available locales, and set the system locale on the command line, as well as to view the current keyboard layout, list available keymaps, and enable a particular keyboard layout on the command line.

- **Chapter 2, Configuring the Date and Time** documents how to manage the system date and time. It explains the difference between a real-time clock and system clock and describes how to use the `timedatectl` utility to display the current settings of the system clock, configure the date and time, change the time zone, and synchronize the system clock with a remote server.

- **Chapter 5, Gaining Privileges** documents how to gain administrative privileges by using the `su` and `sudo` commands.

- **Chapter 11, OpenSSH** describes how to configure an SSH server and how to use the `ssh`, `scp`, and `sftp` client utilities to access it.

- **Chapter 21, Viewing and Managing Log Files** provides an introduction to `journald`. It describes the journal, introduces the `journald` service, and documents how to use the `journalctl` utility to view log entries, enter live view mode, and filter log entries. In addition, this chapter describes how to give non-root users access to system logs and enable persistent storage for log files.
CHAPTER 10. CONFIGURING A SYSTEM FOR ACCESSIBILITY

Accessibility in Red Hat Enterprise Linux 7 is ensured by the Orca screen reader, which is included in the default installation of the operating system. This chapter explains how a system administrator can configure a system to support users with a visual impairment.

Orca reads information from the screen and communicates it to the user using:

- a speech synthesizer, which provides a speech output
- a braille display, which provides a tactile output

For more information on Orca settings, see its help page.

In order that Orca's communication outputs function properly, the system administrator needs to:

- configure the brltty service, as described in Section 10.1, “Configuring the brltty Service”
- switch on the Always Show Universal Access Menu, as described in Section 10.2, “Switch On Always Show Universal Access Menu”
- enable the Festival speech synthesizer, as described in Section 10.3, “Enabling the Festival Speech Synthesis System”

10.1. CONFIGURING THE BRLTTY SERVICE

The Braille display uses the brltty service to provide tactile output for visually impaired users.

Enable the brltty Service

The braille display cannot work unless brltty is running. By default, brltty is disabled. Enable brltty to be started on boot:

```
~]$# systemctl enable brltty.service
```

Authorize Users to Use the Braille Display

To set the users who are authorized to use the braille display, choose one of the following procedures, which have an equal effect. The procedure using the /etc/brltty.conf file is suitable even for the file systems where users or groups cannot be assigned to a file. The procedure using the /etc/brlapi.key file is suitable only for the file systems where users or groups can be assigned to a file.

Procedure 10.1. Setting Access to Braille Display by Using /etc/brltty.conf

1. Open the /etc/brltty.conf file, and find the section called Application Programming Interface Parameters.

2. Specify the users.

   a. To specify one or more individual users, list the users on the following line:

   ```
   api-parameters Auth=user:user_1, user_2, ...
   # Allow some local user
   ```

   b. To specify a user group, enter its name on the following line:
Procedure 10.2. Setting Access to Braille Display by Using /etc/brlapi.key

1. Create the /etc/brlapi.key file.

```
~# mcookie > /etc/brlapi.key
```

2. Change ownership of the /etc/brlapi.key to particular user or group.
   a. To specify an individual user:

```
~# chown user_1 /etc/brlapi.key
```

b. To specify a group:

```
~# chown group_1 /etc/brlapi.key
```

3. Adjust the content of /etc/brltty.conf to include this:

```
api-parameters Auth=keyfile:/etc/brlapi.key
```

Set the Braille Driver

The braille-driver directive in /etc/brltty.conf specifies a two-letter driver identification code of the driver for the braille display.

Procedure 10.3. Setting the Braille Driver

- Decide whether you want to use the autodetection for finding the appropriate braille driver.

  a. If you want to use autodetection, leave braille driver specified to auto, which is the default option.

```
braille-driver auto # autodetect
```

**WARNING**

Autodetection tries all drivers. Therefore, it might take a long time or even fail. For this reason, setting up a particular braille driver is recommended.

b. If you do not want to use the autodetection, specify the identification code of the required braille driver in the braille-driver directive.

Choose the identification code of required braille driver from the list provided in /etc/brltty.conf, for example:
braille-driver xw  # XWindow

You can also set multiple drivers, separated by commas, and autodetection is then performed among them.

Set the Braille Device
The `braille-device` directive in `/etc/brltty.conf` specifies the device to which the braille display is connected. The following device types are supported (see Table 10.1, “Braille Device Types and the Corresponding Syntax”):

Table 10.1. Braille Device Types and the Corresponding Syntax

<table>
<thead>
<tr>
<th>Braille Device Type</th>
<th>Syntax of the Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>serial device</td>
<td>serial:path [a]</td>
</tr>
<tr>
<td>USB device</td>
<td>[serial-number] [b]</td>
</tr>
<tr>
<td>Bluetooth device</td>
<td>bluetooth:address</td>
</tr>
</tbody>
</table>

[a] Relative paths are at `/dev`.
[b] The brackets ([ ]) here indicate optionality.

Examples of settings for particular devices:

```
braille-device serial:ttyS0 # First serial device
braille-device usb:        # First USB device matching
braille driver
braille-device usb:nnnnn   # Specific USB device by serial number
braille-device bluetooth:xx:xx:xx:xx:xx:xx # Specific Bluetooth device by address
```

You can also set multiple devices, separated by commas, and each of them will be probed in turn.
**WARNING**

If the device is connected by a serial-to-USB adapter, setting `braille-device` to `usb:` does not work. In this case, identify the virtual serial device that the kernel has created for the adapter. The virtual serial device can look like this:

```
serial:ttyUSB0
```

You can find the actual device name in the kernel messages on the device plug with the following command:

```
~]# dmesg | fgrep ttyUSB0
```

---

**Set Specific Parameters for Particular Braille Displays**

If you need to set specific parameters for particular braille displays, use the `braille-parameters` directive in `/etc/brltty.conf`. The `braille-parameters` directive passes non-generic parameters through to the braille driver. Choose the required parameters from the list in `/etc/brltty.conf`.

**Set the Text Table**

The `text-table` directive in `/etc/brltty.conf` specifies which text table is used to encode the symbols. Relative paths to text tables are in the `/etc/brltty/Text/` directory.

**Procedure 10.4. Setting the Text Table**

1. Decide whether you want to use the autoselection for finding the appropriate text table.
2. a. If you want to use the autoselection, leave `text-table` specified to `auto`, which is the default option.
   
   ```
   text-table auto  # locale-based autoselection
   ```

   This ensures that local-based autoselection with fallback to `en-nabcc` is performed.

   b. If you do not want to use the autoselection, choose the required `text-table` from the list in `/etc/brltty.conf`.

   For example, to use the text table for American English:

   ```
   text-table en_US  # English (United States)
   ```

**Set the Contraction Table**

The `contraction-table` directive in `/etc/brltty.conf` specifies which table is used to encode the abbreviations. Relative paths to particular contraction tables are in the `/etc/brltty/Contraction/` directory.

Choose the required `contraction-table` from the list in `/etc/brltty.conf`. 

---
For example, to use the contraction table for American English, grade 2:

```
contraction-table en-us-g2  # English (US, grade 2)
```

**WARNING**

If not specified, no contraction table is used.

## 10.2. SWITCH ON ALWAYS SHOW UNIVERSAL ACCESS MENU

To switch on the Orca screen reader, press the `Super+Alt+S` key combination. As a result, the Universal Access Menu icon is displayed on the top bar.

**WARNING**

The icon disappears in case that the user switches off all of the provided options from the Universal Access Menu. Missing icon can cause difficulties to users with a visual impairment. System administrators can prevent the inaccessibility of the icon by switching on the Always Show Universal Access Menu. When the Always Show Universal Access Menu is switched on, the icon is displayed on the top bar even in the situation when all options from this menu are switched off.

**Procedure 10.5. Switching On Always Show Universal Access Menu**

1. Open the Gnome settings menu, and click Universal Access.

2. Switch on Always Show Universal Access Menu.
10.3. ENABLING THE FESTIVAL SPEECH SYNTHESIS SYSTEM

By default, Orca uses the eSpeak speech synthesizer, but it also supports the Festival Speech Synthesis System. Both eSpeak and Festival Speech Synthesis System (Festival) synthesize voice differently. Some users might prefer Festival to the default eSpeak synthesizer. To enable Festival, follow these steps:

Procedure 10.6. Installing Festival and Making it Running on Boot

1. Install Festival:

   ```
   ~]# yum install festival festival-freebsoft-utils
   ```

2. Make Festival running on boot:

   a. Create a new systemd unit file:

   Create a file in the `/etc/systemd/system/` directory and make it executable.

   ```
   ~]# touch /etc/systemd/system/festival.service
   ~]# chmod 664 /etc/systemd/system/festival.service
   ```

   b. Ensure that the script in the `/usr/bin/festival_server` file is used to run Festival.

   Add the following content to the `/etc/systemd/system/festival.service` file:
[Unit]
Description=Festival speech synthesis server
[Service]
ExecStart=/usr/bin/festival_server
Type=simple

c. Notify systemd that a new festival.service file exists:

```
~
# systemctl daemon-reload
~
# systemctl start festival.service
```

d. Enable festival.service:

```
~
# systemctl enable festival.service
```

Choose a Voice for Festival

Festival provides multiples voices.

To make a voice available, install the relevant package from the following list:

- festvox-awb-arctic-hts
- festvox-bdl-arctic-hts
- festvox-clb-arctic-hts
- festvox-kal-diphone
- festvox-ked-diphone
- festvox-rms-arctic-hts
- festvox-sit-arctic-hts
- hispavoces-pal-diphone
- hispavoces-sfl-diphone

To see detailed information about a particular voice:

```
~
# yum info package_name
```

To make the required voice available, install the package with this voice and then reboot:

```
~
# yum install package_name
~
# reboot
```
SSH (Secure Shell) is a protocol which facilitates secure communications between two systems using a client-server architecture and allows users to log in to server host systems remotely. Unlike other remote communication protocols, such as FTP or Telnet, SSH encrypts the login session, rendering the connection difficult for intruders to collect unencrypted passwords.

The ssh program is designed to replace older, less secure terminal applications used to log in to remote hosts, such as telnet or rsh. A related program called scp replaces older programs designed to copy files between hosts, such as rcp. Because these older applications do not encrypt passwords transmitted between the client and the server, avoid them whenever possible. Using secure methods to log in to remote systems decreases the risks for both the client system and the remote host.

Red Hat Enterprise Linux includes the general OpenSSH package, openssh, as well as the OpenSSH server, openssh-server, and client, openssh-clients, packages. Note, the OpenSSH packages require the OpenSSL package openssl-libs, which installs several important cryptographic libraries, enabling OpenSSH to provide encrypted communications.

11.1. THE SSH PROTOCOL

11.1.1. Why Use SSH?

Potential intruders have a variety of tools at their disposal enabling them to disrupt, intercept, and re-route network traffic in an effort to gain access to a system. In general terms, these threats can be categorized as follows:

Interception of communication between two systems
The attacker can be somewhere on the network between the communicating parties, copying any information passed between them. He may intercept and keep the information, or alter the information and send it on to the intended recipient.

This attack is usually performed using a packet sniffer, a rather common network utility that captures each packet flowing through the network, and analyzes its content.

Impersonation of a particular host
Attacker's system is configured to pose as the intended recipient of a transmission. If this strategy works, the user's system remains unaware that it is communicating with the wrong host.

This attack can be performed using a technique known as DNS poisoning, or via so-called IP spoofing. In the first case, the intruder uses a cracked DNS server to point client systems to a maliciously duplicated host. In the second case, the intruder sends falsified network packets that appear to be from a trusted host.

Both techniques intercept potentially sensitive information and, if the interception is made for hostile reasons, the results can be disastrous. If SSH is used for remote shell login and file copying, these security threats can be greatly diminished. This is because the SSH client and server use digital signatures to verify their identity. Additionally, all communication between the client and server systems is encrypted. Attempts to spoof the identity of either side of a communication does not work, since each packet is encrypted using a key known only by the local and remote systems.

11.1.2. Main Features

The SSH protocol provides the following safeguards:
No one can pose as the intended server
After an initial connection, the client can verify that it is connecting to the same server it had connected to previously.

No one can capture the authentication information
The client transmits its authentication information to the server using strong, 128-bit encryption.

No one can intercept the communication
All data sent and received during a session is transferred using 128-bit encryption, making intercepted transmissions extremely difficult to decrypt and read.

Additionally, it also offers the following options:

It provides secure means to use graphical applications over a network
Using a technique called X11 forwarding, the client can forward X11 (X Window System) applications from the server.

It provides a way to secure otherwise insecure protocols
The SSH protocol encrypts everything it sends and receives. Using a technique called port forwarding, an SSH server can become a conduit to securing otherwise insecure protocols, like POP, and increasing overall system and data security.

It can be used to create a secure channel
The OpenSSH server and client can be configured to create a tunnel similar to a virtual private network for traffic between server and client machines.

It supports the Kerberos authentication
OpenSSH servers and clients can be configured to authenticate using the GSSAPI (Generic Security Services Application Program Interface) implementation of the Kerberos network authentication protocol.

11.1.3. Protocol Versions
Two varieties of SSH currently exist: version 1, and newer version 2. The OpenSSH suite under Red Hat Enterprise Linux uses SSH version 2, which has an enhanced key exchange algorithm not vulnerable to the known exploit in version 1. However, for compatibility reasons, the OpenSSH suite does support version 1 connections as well.

IMPORTANT
To ensure maximum security for your connection, it is recommended that only SSH version 2-compatible servers and clients are used whenever possible.

11.1.4. Event Sequence of an SSH Connection
The following series of events help protect the integrity of SSH communication between two hosts.

1. A cryptographic handshake is made so that the client can verify that it is communicating with the correct server.
The transport layer of the connection between the client and remote host is encrypted using a symmetric cipher.

The client authenticates itself to the server.

The client interacts with the remote host over the encrypted connection.

11.1.4.1. Transport Layer

The primary role of the transport layer is to facilitate safe and secure communication between the two hosts at the time of authentication and during subsequent communication. The transport layer accomplishes this by handling the encryption and decryption of data, and by providing integrity protection of data packets as they are sent and received. The transport layer also provides compression, speeding the transfer of information.

Once an SSH client contacts a server, key information is exchanged so that the two systems can correctly construct the transport layer. The following steps occur during this exchange:

- Keys are exchanged
- The public key encryption algorithm is determined
- The symmetric encryption algorithm is determined
- The message authentication algorithm is determined
- The hash algorithm is determined

During the key exchange, the server identifies itself to the client with a unique host key. If the client has never communicated with this particular server before, the server's host key is unknown to the client and it does not connect. OpenSSH gets around this problem by accepting the server's host key. This is done after the user is notified and has both accepted and verified the new host key. In subsequent connections, the server's host key is checked against the saved version on the client, providing confidence that the client is indeed communicating with the intended server. If, in the future, the host key no longer matches, the user must remove the client's saved version before a connection can occur.

**WARNING**

It is possible for an attacker to masquerade as an SSH server during the initial contact since the local system does not know the difference between the intended server and a false one set up by an attacker. To help prevent this, verify the integrity of a new SSH server by contacting the server administrator before connecting for the first time or in the event of a host key mismatch.

SSH is designed to work with almost any kind of public key algorithm or encoding format. After an initial key exchange creates a hash value used for exchanges and a shared secret value, the two systems immediately begin calculating new keys and algorithms to protect authentication and future data sent over the connection.

After a certain amount of data has been transmitted using a given key and algorithm (the exact amount depends on the SSH implementation), another key exchange occurs, generating another set of hash
values and a new shared secret value. Even if an attacker is able to determine the hash and shared secret value, this information is only useful for a limited period of time.

11.1.4.2. Authentication

Once the transport layer has constructed a secure tunnel to pass information between the two systems, the server tells the client the different authentication methods supported, such as using a private key-encoded signature or typing a password. The client then tries to authenticate itself to the server using one of these supported methods.

SSH servers and clients can be configured to allow different types of authentication, which gives each side the optimal amount of control. The server can decide which encryption methods it supports based on its security model, and the client can choose the order of authentication methods to attempt from the available options.

11.1.4.3. Channels

After a successful authentication over the SSH transport layer, multiple channels are opened via a technique called multiplexing\(^1\). Each of these channels handles communication for different terminal sessions and for forwarded X11 sessions.

Both clients and servers can create a new channel. Each channel is then assigned a different number on each end of the connection. When the client attempts to open a new channel, the client sends the channel number along with the request. This information is stored by the server and is used to direct communication to that channel. This is done so that different types of sessions do not affect one another and so that when a given session ends, its channel can be closed without disrupting the primary SSH connection.

Channels also support flow-control, which allows them to send and receive data in an orderly fashion. In this way, data is not sent over the channel until the client receives a message that the channel is open.

The client and server negotiate the characteristics of each channel automatically, depending on the type of service the client requests and the way the user is connected to the network. This allows great flexibility in handling different types of remote connections without having to change the basic infrastructure of the protocol.

11.2. CONFIGURING OPENSSH

11.2.1. Configuration Files

There are two different sets of configuration files: those for client programs (that is, ssh, scp, and sftp), and those for the server (the sshd daemon).

System-wide SSH configuration information is stored in the /etc/ssh/ directory as described in Table 11.1, “System-wide configuration files”. User-specific SSH configuration information is stored in ~/.ssh/ within the user’s home directory as described in Table 11.2, “User-specific configuration files”.

Table 11.1. System-wide configuration files

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
</table>
The SSH client configuration file. Note that it is overridden by
~/.ssh/config if it exists.

The configuration file for the sshd daemon.

The ECDSA private key used by the sshd daemon.

The ECDSA public key used by the sshd daemon.

The RSA private key used by the sshd daemon for version 1 of the
SSH protocol.

The RSA public key used by the sshd daemon for version 1 of the
SSH protocol.

The RSA private key used by the sshd daemon for version 2 of the
SSH protocol.

The RSA public key used by the sshd daemon for version 2 of the
SSH protocol.

The PAM configuration file for the sshd daemon.

Configuration file for the sshd service.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/ssh/moduli</td>
<td>Contains Diffie-Hellman groups used for the Diffie-Hellman key exchange which is critical for constructing a secure transport layer. When keys are exchanged at the beginning of an SSH session, a shared, secret value is created which cannot be determined by either party alone. This value is then used to provide host authentication.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_config</td>
<td>The default SSH client configuration file. Note that it is overridden by ~/.ssh/config if it exists.</td>
</tr>
<tr>
<td>/etc/ssh/sshd_config</td>
<td>The configuration file for the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_ecdsa_key</td>
<td>The ECDSA private key used by the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_ecdsa_key.pub</td>
<td>The ECDSA public key used by the sshd daemon.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_key</td>
<td>The RSA private key used by the sshd daemon for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_key.pub</td>
<td>The RSA public key used by the sshd daemon for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_rsa_key</td>
<td>The RSA private key used by the sshd daemon for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/ssh/ssh_host_rsa_key.pub</td>
<td>The RSA public key used by the sshd daemon for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>/etc/pam.d/sshd</td>
<td>The PAM configuration file for the sshd daemon.</td>
</tr>
<tr>
<td>/etc/sysconfig/sshd</td>
<td>Configuration file for the sshd service.</td>
</tr>
</tbody>
</table>

Table 11.2. User-specific configuration files

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>~/.ssh/authorized_keys</td>
<td>Holds a list of authorized public keys for servers. When the client connects to a server, the server authenticates the client by checking its signed public key stored within this file.</td>
</tr>
<tr>
<td>~/.ssh/id_ecdsa</td>
<td>Contains the ECDSA private key of the user.</td>
</tr>
<tr>
<td>~/.ssh/id_ecdsa.pub</td>
<td>The ECDSA public key of the user.</td>
</tr>
<tr>
<td>File</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>~/.ssh/id_rsa</td>
<td>The RSA private key used by ssh for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/id_rsa.pub</td>
<td>The RSA public key used by ssh for version 2 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/identity</td>
<td>The RSA private key used by ssh for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/identity.pub</td>
<td>The RSA public key used by ssh for version 1 of the SSH protocol.</td>
</tr>
<tr>
<td>~/.ssh/known_hosts</td>
<td>Contains host keys of SSH servers accessed by the user. This file is very important for ensuring that the SSH client is connecting to the correct SSH server.</td>
</tr>
</tbody>
</table>

For information concerning various directives that can be used in the SSH configuration files, see the ssh_config(5) and ssdh_config(5) manual pages.

### 11.2.2. Starting an OpenSSH Server

In order to run an OpenSSH server, you must have the openssh-server package installed. For more information on how to install new packages, see Section 8.2.4, “Installing Packages”.

To start the sshd daemon in the current session, type the following at a shell prompt as root:

```
~$ systemctl start sshd.service
```

To stop the running sshd daemon in the current session, use the following command as root:

```
~$ systemctl stop sshd.service
```

If you want the daemon to start automatically at boot time, type as root:

```
~$ systemctl enable sshd.service
```

Created symlink from /etc/systemd/system/multi-user.target.wants/sshd.service to /usr/lib/systemd/system/sshd.service.

The sshd daemon depends on the network.target target unit, which is sufficient for static configured network interfaces and for default ListenAddress 0.0.0.0 options. To specify different addresses in the ListenAddress directive and to use a slower dynamic network configuration, add dependency on the network-online.target target unit to the sshd.service unit file. To achieve this, create the /etc/systemd/system/sshd.service.d/local.conf file with the following options:

```
[Unit]
Wants=network-online.target
After=network-online.target
```

After this, reload the systemd manager configuration using the following command:
-]# systemctl daemon-reload

For more information on how to manage system services in Red Hat Enterprise Linux, see Chapter 9, *Managing Services with systemd*.

Note that if you reinstall the system, a new set of identification keys will be created. As a result, clients who had connected to the system with any of the OpenSSH tools before the reinstall will see the following message:

@@@ WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED! @@
IT IS POSSIBLE THAT SOMEONE IS DOING SOMETHING NASTY!
Someone could be eavesdropping on you right now (man-in-the-middle attack)!
It is also possible that the RSA host key has just been changed.

To prevent this, you can backup the relevant files from the /etc/ssh/ directory. See Table 11.1, “System-wide configuration files” for a complete list, and restore the files whenever you reinstall the system.

11.2.3. Requiring SSH for Remote Connections

For SSH to be truly effective, using insecure connection protocols should be prohibited. Otherwise, a user's password may be protected using SSH for one session, only to be captured later while logging in using Telnet. Some services to disable include `telnet`, `rsh`, `rlogin`, and `vsftpd`.

For information on how to configure the `vsftpd` service, see Section 15.2, “FTP”. To learn how to manage system services in Red Hat Enterprise Linux 7, read Chapter 9, *Managing Services with systemd*.

11.2.4. Using Key-based Authentication

To improve the system security even further, generate SSH key pairs and then enforce key-based authentication by disabling password authentication. To do so, open the `/etc/ssh/sshd_config` configuration file in a text editor such as `vi` or `nano`, and change the `PasswordAuthentication` option as follows:

```
PasswordAuthentication no
```

If you are working on a system other than a new default installation, check that `PubkeyAuthentication no` has not been set. If connected remotely, not using console or out-of-band access, testing the key-based log in process before disabling password authentication is advised.

To be able to use `ssh`, `scp`, or `sftp` to connect to the server from a client machine, generate an authorization key pair by following the steps below. Note that keys must be generated for each user separately.

Red Hat Enterprise Linux 7 uses SSH Protocol 2 and RSA keys by default (see Section 11.1.3, “Protocol Versions” for more information).

**IMPORTANT**

If you complete the steps as `root`, only `root` will be able to use the keys.
NOTE

If you reinstall your system and want to keep previously generated key pairs, backup the 
~/.ssh/ directory. After reinstalling, copy it back to your home directory. This process
can be done for all users on your system, including root.

11.2.4.1. Generating Key Pairs

To generate an RSA key pair for version 2 of the SSH protocol, follow these steps:

1. Generate an RSA key pair by typing the following at a shell prompt:

   ```
   ~]$ ssh-keygen -t rsa
   Generating public/private rsa key pair.
   Enter file in which to save the key (/home/USER/.ssh/id_rsa):
   ```

2. Press Enter to confirm the default location, ~/.ssh/id_rsa, for the newly created key.

3. Enter a passphrase, and confirm it by entering it again when prompted to do so. For security
   reasons, avoid using the same password as you use to log in to your account.

   After this, you will be presented with a message similar to this:

   ```
   Your identification has been saved in /home/USER/.ssh/id_rsa.
   Your public key has been saved in /home/USER/.ssh/id_rsa.pub.
   The key fingerprint is:
   USER@penguin.example.com
   The key's randomart image is:
   +---[ RSA 2048]----+
   |             E.  |
   |            . .  |
   |             o . |
   |              . .|
   |        S .    . |
   |         + o o ..|
   |          * * +oo|
   |           O +..=|
   |           o*  o.|
   +-----------------+
   ```

4. By default, the permissions of the ~/.ssh/ directory are set to rwx------ or 700 expressed
   in octal notation. This is to ensure that only the USER can view the contents. If required, this
   can be confirmed with the following command:

   ```
   ~]$ ls -ld ~/.ssh
   drwx------. 2 USER USER 54 Nov 25 16:56 /home/USER/.ssh/
   ```

5. To copy the public key to a remote machine, issue a command in the following format:

   ```
   ssh-copy-id user@hostname
   ```

   This will copy the most recently modified ~/.ssh/id*.pub public key if it is not yet installed.
   Alternatively, specify the public key's file name as follows:

   ```
   ssh-copy-id user@hostname ~/.ssh/id_rsa.pub
   ```
To generate an ECDSA key pair for version 2 of the SSH protocol, follow these steps:

1. Generate an ECDSA key pair by typing the following at a shell prompt:

   ```bash
   ~]$ ssh-keygen -t ecdsa
   Generating public/private ecdsa key pair.
   Enter file in which to save the key (/home/USER/.ssh/id_ecdsa):
   
   2. Press Enter to confirm the default location, ~/.ssh/id_ecdsa, for the newly created key.

   3. Enter a passphrase, and confirm it by entering it again when prompted to do so. For security reasons, avoid using the same password as you use to log in to your account.

   After this, you will be presented with a message similar to this:

   Your identification has been saved in /home/USER/.ssh/id_ecdsa.
   Your public key has been saved in /home/USER/.ssh/id_ecdsa.pub.
   The key fingerprint is:
   USER@penguin.example.com
   The key's randomart image is:
   +---[ECDSA  256]----+
   | . +o +. |
   | . =.o |
   | . o o + .|
   | + + o + |
   | S o o oE.|
   | + oo+. |
   | + o |
   | |
   +-----------------+

4. By default, the permissions of the ~/.ssh/ directory are set to rwx------ or 700 expressed in octal notation. This is to ensure that only the USER can view the contents. If required, this can be confirmed with the following command:

   ```bash
   ~]$ ls -ld ~/.ssh
   ~]$ ls -ld ~/.ssh/
   drwx------. 2 USER USER 54 Nov 25 16:56 /home/USER/.ssh/
   
   5. To copy the public key to a remote machine, issue a command in the following format:

   ```bash
   ssh-copy-id USER@hostname
   ```

   This will copy the most recently modified ~/.ssh/id*.pub public key if it is not yet installed. Alternatively, specify the public key's file name as follows:

   ```bash
   ssh-copy-id -i ~/.ssh/id_rsa.pub user@hostname
   ```

   This will copy the content of ~/.ssh/id_rsa.pub into the ~/.ssh/authorized_keys file on the machine to which you want to connect. If the file already exists, the keys are appended to its end.
ssh-copy-id -i ~/.ssh/id_ecdsa.pub USER@hostname

This will copy the content of ~/.ssh/id_ecdsa.pub into the ~/.ssh/authorized_keys on the machine to which you want to connect. If the file already exists, the keys are appended to its end.

See Section 11.2.4.2, “Configuring ssh-agent” for information on how to set up your system to remember the passphrase.

IMPORTANT

The private key is for your personal use only, and it is important that you never give it to anyone.

11.2.4.2. Configuring ssh-agent

To store your passphrase so that you do not have to enter it each time you initiate a connection with a remote machine, you can use the ssh-agent authentication agent. If you are running GNOME, you can configure it to prompt you for your passphrase whenever you log in and remember it during the whole session. Otherwise you can store the passphrase for a certain shell prompt.

To save your passphrase during your GNOME session, follow these steps:

1. Make sure you have the openssh-askpass package installed. If not, see Section 8.2.4, “Installing Packages” for more information on how to install new packages in Red Hat Enterprise Linux.

2. Press the Super key to enter the Activities Overview, type Startup Applications and then press Enter. The Startup Applications Preferences tool appears. The tab containing a list of available startup programs will be shown by default. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Space bar.
3. Click the **Add** button on the right, and enter `/usr/bin/ssh-add` in the **Command** field.

4. Click **Add** and make sure the checkbox next to the newly added item is selected.
5. Log out and then log back in. A dialog box will appear prompting you for your passphrase. From this point on, you should not be prompted for a password by ssh, scp, or sftp.

To save your passphrase for a certain shell prompt, use the following command:

```
~]$ ssh-add
Enter passphrase for /home/USER/.ssh/id_rsa:
```

Note that when you log out, your passphrase will be forgotten. You must execute the command each time you log in to a virtual console or a terminal window.

### 11.3. OPENSSH CLIENTS
To connect to an OpenSSH server from a client machine, you must have the openssh-clients package installed (see Section 8.2.4, “Installing Packages” for more information on how to install new packages in Red Hat Enterprise Linux).

11.3.1. Using the ssh Utility

The ssh utility allows you to log in to a remote machine and execute commands there. It is a secure replacement for the rlogin, rsh, and telnet programs.

Similarly to the telnet command, log in to a remote machine by using the following command:

```
ssh hostname
```

For example, to log in to a remote machine named `penguin.example.com`, type the following at a shell prompt:

```
~]$ ssh penguin.example.com
```

This will log you in with the same user name you are using on the local machine. If you want to specify a different user name, use a command in the following form:

```
ssh username@hostname
```

For example, to log in to `penguin.example.com` as `USER`, type:

```
~]$ ssh USER@penguin.example.com
```

The first time you initiate a connection, you will be presented with a message similar to this:

```
The authenticity of host 'penguin.example.com' can't be established. ECDSA key fingerprint is 256 da:24:43:0b:2e:c1:3f:a1:84:13:92:01:52:b4:84:ff. Are you sure you want to continue connecting (yes/no)?
```

Users should always check if the fingerprint is correct before answering the question in this dialog. The user can ask the administrator of the server to confirm the key is correct. This should be done in a secure and previously agreed way. If the user has access to the server’s host keys, the fingerprint can be checked by using the `ssh-keygen` command as follows:

```
~]# ssh-keygen -l -f /etc/ssh/ssh_host_ecdsa_key.pub
```

Type yes to accept the key and confirm the connection. You will see a notice that the server has been added to the list of known hosts, and a prompt asking for your password:

```
Warning: Permanently added 'penguin.example.com' (ECDSA) to the list of known hosts.
USER@penguin.example.com's password:
```
IMPORTANT

If the SSH server's host key changes, the client notifies the user that the connection cannot proceed until the server's host key is deleted from the ~/.ssh/known_hosts file. Before doing this, however, contact the system administrator of the SSH server to verify the server is not compromised.

To remove a key from the ~/.ssh/known_hosts file, issue a command as follows:

```
~]# ssh-keygen -R penguin.example.com
# Host penguin.example.com found: line 15 type ECDSA
/home/USER/.ssh/known_hosts updated.
Original contents retained as /home/USER/.ssh/known_hosts.old
```

After entering the password, you will be provided with a shell prompt for the remote machine.

Alternatively, the ssh program can be used to execute a command on the remote machine without logging in to a shell prompt:

```
ssh [username@]hostname command
```

For example, the /etc/redhat-release file provides information about the Red Hat Enterprise Linux version. To view the contents of this file on penguin.example.com, type:

```
~]# ssh USER@penguin.example.com cat /etc/redhat-release
USER@penguin.example.com's password:
Red Hat Enterprise Linux Server release 7.0 (Maipo)
```

After you enter the correct password, the user name will be displayed, and you will return to your local shell prompt.

11.3.2. Using the scp Utility

scp can be used to transfer files between machines over a secure, encrypted connection. In its design, it is very similar to rcp.

To transfer a local file to a remote system, use a command in the following form:

```
scp localfile username@hostname:remotefile
```

For example, if you want to transfer taglist.vim to a remote machine named penguin.example.com, type the following at a shell prompt:

```
~]# scp taglist.vim USER@penguin.example.com:.vim/plugin/taglist.vim
USER@penguin.example.com's password: taglist.vim                                   100%  144KB 144.5KB/s 00:00
```

Multiple files can be specified at once. To transfer the contents of .vim/plugin/ to the same directory on the remote machine penguin.example.com, type the following command:

```
~]# scp .vim/plugin/* USER@penguin.example.com:.vim/plugin/
```
To transfer a remote file to the local system, use the following syntax:

```bash
scp username@hostname:remotefile localfile
```

For instance, to download the `.vimrc` configuration file from the remote machine, type:

```bash
~$ scp USER@penguin.example.com:.vimrc .vimrc
```

11.3.3. Using the sftp Utility

The `sftp` utility can be used to open a secure, interactive FTP session. In its design, it is similar to `ftp` except that it uses a secure, encrypted connection.

To connect to a remote system, use a command in the following form:

```bash
sftp username@hostname
```

For example, to log in to a remote machine named `penguin.example.com` with `USER` as a user name, type:

```bash
~$ sftp USER@penguin.example.com
```

After you enter the correct password, you will be presented with a prompt. The `sftp` utility accepts a set of commands similar to those used by `ftp` (see Table 11.3, “A selection of available sftp commands”).

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ls</code> [directory]</td>
<td>List the content of a remote directory. If none is supplied, a current working directory is used by default.</td>
</tr>
<tr>
<td><code>cd</code> directory</td>
<td>Change the remote working directory to directory.</td>
</tr>
<tr>
<td><code>mkdir</code> directory</td>
<td>Create a remote directory.</td>
</tr>
</tbody>
</table>
### Command Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rmdir path</td>
<td>Remove a remote directory.</td>
</tr>
<tr>
<td>put localfile [remotefile]</td>
<td>Transfer localfile to a remote machine.</td>
</tr>
<tr>
<td>get remotefile [localfile]</td>
<td>Transfer remotefile from a remote machine.</td>
</tr>
</tbody>
</table>

For a complete list of available commands, see the `sftp(1)` manual page.

### 11.4. MORE THAN A SECURE SHELL

A secure command-line interface is just the beginning of the many ways SSH can be used. Given the proper amount of bandwidth, X11 sessions can be directed over an SSH channel. Or, by using TCP/IP forwarding, previously insecure port connections between systems can be mapped to specific SSH channels.

#### 11.4.1. X11 Forwarding

To open an X11 session over an SSH connection, use a command in the following form:

```
ssh -Y username@hostname
```

For example, to log in to a remote machine named `penguin.example.com` with `USER` as a user name, type:

```
~]$ ssh -Y USER@penguin.example.com
```

USER@penguin.example.com's password:

When an X program is run from the secure shell prompt, the SSH client and server create a new secure channel, and the X program data is sent over that channel to the client machine transparently.

Note that the X Window system must be installed on the remote system before X11 forwarding can take place. Enter the following command as `root` to install the X11 package group:

```
~]$# yum group install "X Window System"
```

For more information on package groups, see Section 8.3, “Working with Package Groups”.

X11 forwarding can be very useful. For example, X11 forwarding can be used to create a secure, interactive session of the Print Settings utility. To do this, connect to the server using `ssh` and type:

```
~]$ system-config-printer &
```

The Print Settings tool will appear, allowing the remote user to safely configure printing on the remote system.

#### 11.4.2. Port Forwarding

SSH can secure otherwise insecure TCP/IP protocols via port forwarding. When using this technique, the SSH server becomes an encrypted conduit to the SSH client.
Port forwarding works by mapping a local port on the client to a remote port on the server. SSH can map any port from the server to any port on the client. Port numbers do not need to match for this technique to work.

NOTE

Setting up port forwarding to listen on ports below 1024 requires root level access.

To create a TCP/IP port forwarding channel which listens for connections on the localhost, use a command in the following form:

```bash
ssh -L local-port:remote-hostname:remote-port username@hostname
```

For example, to check email on a server called `mail.example.com` using POP3 through an encrypted connection, use the following command:

```bash
~$ ssh -L 1100:mail.example.com:110 mail.example.com
```

Once the port forwarding channel is in place between the client machine and the mail server, direct a POP3 mail client to use port 1100 on the localhost to check for new email. Any requests sent to port 1100 on the client system will be directed securely to the `mail.example.com` server.

If `mail.example.com` is not running an SSH server, but another machine on the same network is, SSH can still be used to secure part of the connection. However, a slightly different command is necessary:

```bash
~$ ssh -L 1100:mail.example.com:110 other.example.com
```

In this example, POP3 requests from port 1100 on the client machine are forwarded through the SSH connection on port 22 to the SSH server, `other.example.com`. Then, `other.example.com` connects to port 110 on `mail.example.com` to check for new email. Note that when using this technique, only the connection between the client system and `other.example.com` SSH server is secure.

Port forwarding can also be used to get information securely through network firewalls. If the firewall is configured to allow SSH traffic via its standard port (that is, port 22) but blocks access to other ports, a connection between two hosts using the blocked ports is still possible by redirecting their communication over an established SSH connection.

IMPORTANT

Using port forwarding to forward connections in this manner allows any user on the client system to connect to that service. If the client system becomes compromised, the attacker also has access to forwarded services.

System administrators concerned about port forwarding can disable this functionality on the server by specifying a `No` parameter for the `AllowTcpForwarding` line in `/etc/ssh/sshd_config` and restarting the `sshd` service.

11.5. ADDITIONAL RESOURCES
For more information on how to configure or connect to an OpenSSH server on Red Hat Enterprise Linux, see the resources listed below.

**Installed Documentation**

- sshd(8) – The manual page for the sshd daemon documents available command line options and provides a complete list of supported configuration files and directories.

- ssh(1) – The manual page for the ssh client application provides a complete list of available command line options and supported configuration files and directories.

- scp(1) – The manual page for the scp utility provides a more detailed description of this utility and its usage.

- sftp(1) – The manual page for the sftp utility.

- ssh-keygen(1) – The manual page for the ssh-keygen utility documents in detail how to use it to generate, manage, and convert authentication keys used by ssh.

- ssh_config(5) – The manual page named ssh_config documents available SSH client configuration options.

- sshd_config(5) – The manual page named sshd_config provides a full description of available SSH daemon configuration options.

**Online Documentation**

- OpenSSH Home Page — The OpenSSH home page containing further documentation, frequently asked questions, links to the mailing lists, bug reports, and other useful resources.

- OpenSSL Home Page — The OpenSSL home page containing further documentation, frequently asked questions, links to the mailing lists, and other useful resources.

**See Also**

- Chapter 5, Gaining Privileges documents how to gain administrative privileges by using the su and sudo commands.

- Chapter 9, Managing Services with systemd provides more information on systemd and documents how to use the systemctl command to manage system services.

---

[1] A multiplexed connection consists of several signals being sent over a shared, common medium. With SSH, different channels are sent over a common secure connection.
CHAPTER 12. TIGERVNC

TigerVNC (Tiger Virtual Network Computing) is a system for graphical desktop sharing which allows you to remotely control other computers.

TigerVNC works on the client-server principle: a server shares its output (vncserver) and a client (vncviewer) connects to the server.

NOTE

Unlike in previous Red Hat Enterprise Linux distributions, TigerVNC in Red Hat Enterprise Linux 7 uses the systemd system management daemon for its configuration. The /etc/sysconfig/vncserver configuration file has been replaced by /etc/systemd/system/vncserver@.service.

12.1. VNC SERVER

vncserver is a utility which starts a VNC (Virtual Network Computing) desktop. It runs Xvnc with appropriate options and starts a window manager on the VNC desktop. vncserver allows users to run separate sessions in parallel on a machine which can then be accessed by any number of clients from anywhere.

12.1.1. Installing VNC Server

To install the TigerVNC server, issue the following command as root:

```
~
```# yum install tigervnc-server

12.1.2. Configuring VNC Server

The VNC server can be configured to start a display for one or more users, provided that accounts for the users exist on the system, with optional parameters such as for display settings, network address and port, and security settings.

Procedure 12.1. Configuring a VNC Display for a Single User

1. A configuration file named /etc/systemd/system/vncserver@.service is required. To create this file, copy the /usr/lib/systemd/system/vncserver@.service file as root:

```
~
```# cp /usr/lib/systemd/system/vncserver@.service
/etc/systemd/system/vncserver@.service

There is no need to include the display number in the file name because systemd automatically creates the appropriately named instance in memory on demand, replacing '%i' in the service file by the display number. For a single user it is not necessary to rename the file. For multiple users, a uniquely named service file for each user is required, for example, by adding the user name to the file name in some way. See Section 12.1.2.1, "Configuring VNC Server for Two Users" for details.

2. Edit /etc/systemd/system/vncserver@.service, replacing USER with the actual user name. Leave the remaining lines of the file unmodified. The -geometry argument specifies the size of the VNC desktop to be created; by default, it is set to 1024x768.
ExecStart=/usr/sbin/runuser -l USER -c "/usr/bin/vncserver %i -geometry 1280x1024"
PIDFile=/home/USER/.vnc/%H%i.pid

3. Save the changes.

4. To make the changes take effect immediately, issue the following command:

```bash
~]$ systemctl daemon-reload
```

5. Set the password for the user or users defined in the configuration file. Note that you need to switch from root to USER first.

```bash
~]$ su - USER
~]$ vncpasswd
Password:
Verify:
```

**IMPORTANT**

The stored password is not encrypted; anyone who has access to the password file can find the plain-text password.

Proceed to Section 12.1.3, “Starting VNC Server”.

### 12.1.2.1. Configuring VNC Server for Two Users

If you want to configure more than one user on the same machine, create different template-type service files, one for each user.

1. Create two service files, for example `vncserver-USER_1@.service` and `vncserver-USER_2@.service`. In both these files substitute USER with the correct user name.

2. Set passwords for both users:

```bash
~]$ su - USER_1
~]$ vncpasswd
Password:
Verify:
~]$ su - USER_2
~]$ vncpasswd
Password:
Verify:
```

### 12.1.3. Starting VNC Server

To start or enable the service, specify the display number directly in the command. The file configured above in Procedure 12.1, “Configuring a VNC Display for a Single User” works as a template, in which %i is substituted with the display number by systemd. With a valid display number, execute the following command:
You can also enable the service to start automatically at system start. Then, when you log in, `vncserver` is automatically started. As `root`, issue a command as follows:

```
-]# systemctl enable vncserver@:display_number.service
```

At this point, other users are able to use a VNC viewer program to connect to the VNC server using the display number and password defined. Provided a graphical desktop is installed, an instance of that desktop will be displayed. It will not be the same instance as that currently displayed on the target machine.

### 12.1.3.1. Configuring VNC Server for Two Users and Two Different Displays

For the two configured VNC servers, `vncserver-USER_1@.service` and `vncserver-USER_2@.service`, you can enable different display numbers. For example, the following commands will cause a VNC server for USER_1 to start on display 3, and a VNC server for USER_2 to start on display 5:

```
-]# systemctl start vncserver-USER_1@:3.service
-]# systemctl start vncserver-USER_2@:5.service
```

### 12.1.4. VNC setup based on xinetd with XDMCP for GDM

VNC setup based on xinetd with X Display Manager Control Protocol (XDMCP) for GDM is a useful setup for client systems that consist mainly of thin clients. After the setup, clients are able to access the GDM login window and log in to any system account. The prerequisite for the setup is that the gdm, vnc, vnc-server & and xinetd packages are installed.

```
-]# yum install gdm tigervnc tigervnc-server xinetd
```

Service xinetd must be enabled.

```
-]# systemctl enable xinetd.service
```

System default target unit should be `graphical.target`. To get the currently set default target unit, use:

```
-]# systemctl get-default
```

The default target unit can be changed by using:

```
-]# systemctl set-default target_name
```

**Procedure 12.2. Accessing the GDM login window and logging in**

1. Set up GDM to enable XDMCP by editing the `/etc/gdm/custom.conf` configuration file:

   ```
   [xdmcp]
   Enable=true
   ```

2. Create a file called `/etc/xinetd.d/xvncserver` with the following content:
service service_name
{
  disable = no
  protocol = tcp
  socket_type = stream
  wait = no
  user = nobody
  server = /usr/bin/Xvnc
  server_args = -inetd -query localhost -once -geometry
    selected_geometry -depth selected_depth securitytypes=none
}

In the server_args section, the -query localhost option will make each Xvnc instance query localhost for an xdmcp session. The -depth option specifies the pixel depth (in bits) of the VNC desktop to be created. Acceptable values are 8, 15, 16 and 24 - any other values are likely to cause unpredictable behavior of applications.

3. Edit file /etc/services to have the service defined. To do this, append the following snippet to the /etc/services file:

```
# VNC xinetd GDM base
service_name 5950/tcp
```

4. To ensure that the configuration changes take effect, reboot the machine.

Alternatively, you can run the following. Change init levels to 3 and back to 5 to force gdm to reload.

```
# init 3
# init 5
```

Verify that gdm is listening on UDP port 177.

```
# netstat -anu|grep 177
udp 0 0 0.0.0.0:177 0.0.0.0:*
```

Restart the xinetd service.

```
~]# systemctl restart xinetd.service
```

Verify that the xinetd service has loaded the new services.

```
# netstat -anpt|grep 595
tcp 0 0 ::::5950 ::::*
LISTEN 3119/xinetd
```

5. Test the setup using a vncviewer command:

```
# vncviewer localhost:5950
```

The command will launch a VNC session to the localhost where no password is asked. You will see a GDM login screen, and you will be able to log in to any user account on the system with a valid user name and password. Then you can run the same test on remote connections.
Configure firewall for the setup. Run the firewall configuration tool and add TCP port 5950 to allow incoming connections to the system.

```
~# firewall-cmd --permanent --zone=public --add-port=5950/tcp
~# firewall-cmd --reload
```

12.1.5. Terminating a VNC Session

Similarly to enabling the vncserver service, you can disable the automatic start of the service at system start:

```
~# systemctl disable vncserver@:display_number.service
```

Or, when your system is running, you can stop the service by issuing the following command as root:

```
~# systemctl stop vncserver@:display_number.service
```

12.2. SHARING AN EXISTING DESKTOP

By default a logged in user has a desktop provided by X Server on display 0. A user can share their desktop using the TigerVNC server x0vncserver.

Procedure 12.3. Sharing an X Desktop

To share the desktop of a logged in user, using the x0vncserver, proceed as follows:

1. Enter the following command as root

```
~# yum install tigervnc-server
```

2. Set the VNC password for the user:

```
~$ vncpasswd
Password: 
Verify: 
```

3. Enter the following command as that user:

```
~$ x0vncserver -PasswordFile=.vnc/passwd -AlwaysShared=1
```

Provided the firewall is configured to allow connections to port 5900, the remote viewer can now connect to display 0, and view the logged in users desktop. See Section 12.3.2.1, “Configuring the Firewall for VNC” for information on how to configure the firewall.

12.3. VNC VIEWER

vncviewer is a program which shows the graphical user interfaces and controls the vncserver remotely.

For operating the vncviewer, there is a pop-up menu containing entries which perform various actions such as switching in and out of full-screen mode or quitting the viewer. Alternatively, you can
operate \texttt{vncviewer} through the terminal. Enter \texttt{vncviewer -h} on the command line to list \texttt{vncviewer}'s parameters.

\subsection*{12.3.1. Installing VNC Viewer}

To install the TigerVNC client, \texttt{vncviewer}, issue the following command as \texttt{root}:

\begin{verbatim}
~\$ yum install tigervnc
\end{verbatim}

\subsection*{12.3.2. Connecting to VNC Server}

Once the VNC server is configured, you can connect to it from any VNC viewer.

\textbf{Procedure 12.4. Connecting to a VNC Server Using a GUI}

1. Enter the \texttt{vncviewer} command with no arguments, the \texttt{VNC Viewer: Connection Details} utility appears. It prompts for a VNC server to connect to.

2. If required, to prevent disconnecting any existing VNC connections to the same display, select the option to allow sharing of the desktop as follows:
   a. Select the \texttt{Options} button.
   b. Select the \texttt{Misc.} tab.
   c. Select the \texttt{Shared} button.
   d. Press \texttt{OK} to return to the main menu.

3. Enter an address and display number to connect to:

   \begin{verbatim}
   address:display_number
   \end{verbatim}

4. Press \texttt{Connect} to connect to the VNC server display.

5. You will be prompted to enter the VNC password. This will be the VNC password for the user corresponding to the display number unless a global default VNC password was set.

   A window appears showing the VNC server desktop. Note that this is not the desktop the normal user sees, it is an Xvnc desktop.

\textbf{Procedure 12.5. Connecting to a VNC Server Using the CLI}

1. Enter the \texttt{viewer} command with the address and display number as arguments:

   \begin{verbatim}
   vncviewer address:display_number
   \end{verbatim}

   Where \texttt{address} is an IP address or host name.

2. Authenticate yourself by entering the VNC password. This will be the VNC password for the user corresponding to the display number unless a global default VNC password was set.

3. A window appears showing the VNC server desktop. Note that this is not the desktop the normal user sees, it is the Xvnc desktop.
12.3.2.1. Configuring the Firewall for VNC

When using a non-encrypted connection, `firewalld` might block the connection. To allow `firewalld` to pass the VNC packets, you can open specific ports to TCP traffic. When using the `-via` option, traffic is redirected over SSH which is enabled by default in `firewalld`.

**NOTE**

The default port of VNC server is 5900. To reach the port through which a remote desktop will be accessible, sum the default port and the user's assigned display number. For example, for the second display: 2 + 5900 = 5902.

For displays 0 to 3, make use of `firewalld`'s support for the VNC service by means of the `service` option as described below. Note that for display numbers greater than 3, the corresponding ports will have to be opened specifically as explained in Procedure 12.7, “Opening Ports in firewalld”.

**Procedure 12.6. Enabling VNC Service in firewalld**

1. Run the following command to see the information concerning `firewalld` settings:

   ```bash
   ~]$ firewall-cmd --list-all
   ```

2. To allow all VNC connections from a specific address, use a command as follows:

   ```bash
   ~]$ firewall-cmd --add-rich-rule='rule family="ipv4" source address="192.168.122.116" service name=vnc-server accept'
   ```

   Note that these changes will not persist after the next system start. To make permanent changes to the firewall, repeat the commands adding the `--permanent` option. See the Red Hat Enterprise Linux 7 Security Guide for more information on the use of firewall rich language commands.

3. To verify the above settings, use a command as follows:

   ```bash
   ~]$ firewall-cmd --list-all
   public (default, active)
   interfaces: bond0 bond0.192
   sources:
   services: dhcpv6-client ssh
   ports:
   masquerade: no
   forward-ports:
   icmp-blocks:
   rich rules:
   rule family="ipv4" source address="192.168.122.116" service name="vnc-server" accept
   ```

To open a specific port or range of ports make use of the `--add-port` option to the `firewall-cmd` command Line tool. For example, VNC display 4 requires port 5904 to be opened for TCP traffic.

**Procedure 12.7. Opening Ports in firewalld**
1. To open a port for TCP traffic in the public zone, issue a command as root as follows:

```bash
~$ firewall-cmd --zone=public --add-port=5904/tcp
success
```

2. To view the ports that are currently open for the public zone, issue a command as follows:

```bash
~$ firewall-cmd --zone=public --list-ports
5904/tcp
```

A port can be removed using the `firewall-cmd --zone=zone --remove-port=number/protocol` command.

Note that these changes will not persist after the next system start. To make permanent changes to the firewall, repeat the commands adding the `--permanent` option. For more information on opening and closing ports in `firewalld`, see the Red Hat Enterprise Linux 7 Security Guide.

### 12.3.3. Connecting to VNC Server Using SSH

VNC is a clear text network protocol with no security against possible attacks on the communication. To make the communication secure, you can encrypt your server-client connection by using the `-via` option. This will create an SSH tunnel between the VNC server and the client.

The format of the command to encrypt a VNC server-client connection is as follows:

```bash
vncviewer -via user@host:display_number
```

**Example 12.1. Using the -via Option**

1. To connect to a VNC server using SSH, enter a command as follows:

```bash
~$ vncviewer -via USER_2@192.168.2.101:3
```

2. When you are prompted to, type the password, and confirm by pressing Enter.

3. A window with a remote desktop appears on your screen.

**Restricting VNC Access**

If you prefer only encrypted connections, you can prevent unencrypted connections altogether by using the `--localhost` option in the `systemd.service` file, the `ExecStart` line:

```bash
ExecStart=/usr/sbin/runuser -l user -c "/usr/bin/vncserver --localhost %i"
```

This will stop `vncserver` from accepting connections from anything but the local host and port-forwarded connections sent using SSH as a result of the `-via` option.

For more information on using SSH, see Chapter 11, *OpenSSH*.

### 12.4. ADDITIONAL RESOURCES

For more information about TigerVNC, see the resources listed below.
Installed Documentation

- `vncserver(1)` – The manual page for the VNC server utility.
- `vncviewer(1)` – The manual page for the VNC viewer.
- `vncpasswd(1)` – The manual page for the VNC password command.
- `Xvnc(1)` – The manual page for the Xvnc server configuration options.
- `x0vncserver(1)` – The manual page for the TigerVNC server for sharing existing X servers.
This part discusses various topics related to servers such as how to set up a web server or share files and directories over a network.
CHAPTER 13. WEB SERVERS

A web server is a network service that serves content to a client over the web. This typically means web pages, but any other documents can be served as well. Web servers are also known as HTTP servers, as they use the hypertext transport protocol (HTTP).

13.1. THE APACHE HTTP SERVER

The web server available in Red Hat Enterprise Linux 7 is version 2.4 of the Apache HTTP Server, httpd, an open source web server developed by the Apache Software Foundation.

If you are upgrading from a previous release of Red Hat Enterprise Linux, you will need to update the httpd service configuration accordingly. This section reviews some of the newly added features, outlines important changes between Apache HTTP Server 2.4 and version 2.2, and guides you through the update of older configuration files.

13.1.1. Notable Changes

The Apache HTTP Server in Red Hat Enterprise Linux 7 has the following changes compared to Red Hat Enterprise Linux 6:

httpd Service Control

With the migration away from SysV init scripts, server administrators should switch to using the apachectl and systemctl commands to control the service, in place of the service command. The following examples are specific to the httpd service.

The command:

service httpd graceful

is replaced by

apachectl graceful

The systemd unit file for httpd has different behavior from the init script as follows:

- A graceful restart is used by default when the service is reloaded.
- A graceful stop is used by default when the service is stopped.

The command:

service httpd configtest

is replaced by

apachectl configtest

Private /tmp

To enhance system security, the systemd unit file runs the httpd daemon using a private /tmp directory, separate to the system /tmp directory.
Configuration Layout

Configuration files which load modules are now placed in the `/etc/httpd/conf.modules.d/` directory. Packages that provide additional loadable modules for `httpd`, such as `php`, will place a file in this directory. An `Include` directive before the main section of the `/etc/httpd/conf/httpd.conf` file is used to include files within the `/etc/httpd/conf.modules.d/` directory. This means any configuration files within `conf.modules.d/` are processed before the main body of `httpd.conf`. An `IncludeOptional` directive for files within the `/etc/httpd/conf.d/` directory is placed at the end of the `httpd.conf` file. This means the files within `/etc/httpd/conf.d/` are now processed after the main body of `httpd.conf`.

Some additional configuration files are provided by the `httpd` package itself:

- `/etc/httpd/conf.d/autoindex.conf` – This configures mod_autoindex directory indexing.
- `/etc/httpd/conf.d/userdir.conf` – This configures access to user directories, for example, `http://example.com/~username/`; such access is disabled by default for security reasons.
- `/etc/httpd/conf.d/welcome.conf` – As in previous releases, this configures the welcome page displayed for `http://localhost/` when no content is present.

Default Configuration

A minimal `httpd.conf` file is now provided by default. Many common configuration settings, such as `Timeout` or `KeepAlive` are no longer explicitly configured in the default configuration; hard-coded settings will be used instead, by default. The hard-coded default settings for all configuration directives are specified in the manual. See the section called “Installable Documentation” for more information.

Incompatible Syntax Changes

If migrating an existing configuration from `httpd 2.2` to `httpd 2.4`, a number of backwards-incompatible changes to the `httpd` configuration syntax were made which will require changes. See the following Apache document for more information on upgrading
http://httpd.apache.org/docs/2.4/upgrading.html

Processing Model

In previous releases of Red Hat Enterprise Linux, different `multi-processing models` (MPM) were made available as different `httpd` binaries: the forked model, “prefork”, as `/usr/sbin/httpd`, and the thread-based model “worker” as `/usr/sbin/httpd.worker`.

In Red Hat Enterprise Linux 7, only a single `httpd` binary is used, and three MPMs are available as loadable modules: worker, prefork (default), and event. Edit the configuration file `/etc/httpd/conf.modules.d/00-mpm.conf` as required, by adding and removing the comment character `#` so that only one of the three MPM modules is loaded.

Packaging Changes

The LDAP authentication and authorization modules are now provided in a separate sub-package, `mod_ldap`. The new module `mod_session` and associated helper modules are provided in a new sub-package, `mod_session`. The new modules `mod_proxy_html` and `mod_xml2enc` are provided in a new sub-package, `mod_proxy_html`. These packages are all in the Optional channel.
NOTE

Before subscribing to the Optional and Supplementary channels see the Scope of Coverage Details. If you decide to install packages from these channels, follow the steps documented in the article called How to access Optional and Supplementary channels, and -devel packages using Red Hat Subscription Manager (RHSM)? on the Red Hat Customer Portal.

Packaging Filesystem Layout

The /var/cache/mod_proxy/ directory is no longer provided; instead, the /var/cache/httpd/ directory is packaged with a proxy and ssl subdirectory.

Packaged content provided with httpd has been moved from /var/www/ to /usr/share/httpd:

- /usr/share/httpd/icons/ — The directory containing a set of icons used with directory indices, previously contained in /var/www/icons/, has moved to /usr/share/httpd/icons/. Available at http://localhost/icons/ in the default configuration; the location and the availability of the icons is configurable in the /etc/httpd/conf.d/autoindex.conf file.

- /usr/share/httpd/error/ — The /var/www/error/ has moved to /usr/share/httpd/error/. Custom multi-language HTTP error pages. Not configured by default, the example configuration file is provided at /usr/share/doc/httpd-VERSION/httpd-multilang-errordoc.conf.

Authentication, Authorization and Access Control

The configuration directives used to control authentication, authorization and access control have changed significantly. Existing configuration files using the Order, Deny and Allow directives should be adapted to use the new Require syntax. See the following Apache document for more information http://httpd.apache.org/docs/2.4/howto/auth.html

suexec

To improve system security, the suexec binary is no longer installed as if by the root user; instead, it has file system capability bits set which allow a more restrictive set of permissions. In conjunction with this change, the suexec binary no longer uses the /var/log/httpd/suexec.log logfile. Instead, log messages are sent to syslog; by default these will appear in the /var/log/secure logfile.

Module Interface

Third-party binary modules built against httpd 2.2 are not compatible with httpd 2.4 due to changes to the httpd module interface. Such modules will need to be adjusted as necessary for the httpd 2.4 module interface, and then rebuilt. A detailed list of the API changes in version 2.4 is available here: http://httpd.apache.org/docs/2.4/developer/new_api_2_4.html.
The `apxs` binary used to build modules from source has moved from `/usr/sbin/apxs` to `/usr/bin/apxs`.

**Removed modules**

List of `httpd` modules removed in Red Hat Enterprise Linux 7:

- `mod_auth_mysql, mod_auth_pgsql`
  - `httpd 2.4` provides SQL database authentication support internally in the `mod_authn_dbd` module.

- `mod_perl`
  - `mod_perl` is not officially supported with `httpd 2.4` by upstream.

- `mod_authz_ldap`
  - `httpd 2.4` provides LDAP support in sub-package `mod_ldap` using `mod_authnz_ldap`.

### 13.1.2. Updating the Configuration

To update the configuration files from the Apache HTTP Server version 2.2, take the following steps:

1. Make sure all module names are correct, since they may have changed. Adjust the `LoadModule` directive for each module that has been renamed.

2. Recompile all third party modules before attempting to load them. This typically means authentication and authorization modules.

3. If you use the `mod_userdir` module, make sure the `UserDir` directive indicating a directory name (typically `public_html`) is provided.

4. If you use the Apache HTTP Secure Server, see Section 13.1.8, “Enabling the mod_ssl Module” for important information on enabling the Secure Sockets Layer (SSL) protocol.

Note that you can check the configuration for possible errors by using the following command:

```
-]# apachectl configtest
Syntax OK
```

For more information on upgrading the Apache HTTP Server configuration from version 2.2 to 2.4, see [http://httpd.apache.org/docs/2.4/upgrading.html](http://httpd.apache.org/docs/2.4/upgrading.html).

### 13.1.3. Running the `httpd` Service

This section describes how to start, stop, restart, and check the current status of the Apache HTTP Server. To be able to use the `httpd` service, make sure you have the `httpd` installed. You can do so by using the following command:

```
-]# yum install httpd
```

For more information on the concept of targets and how to manage system services in Red Hat Enterprise Linux in general, see Chapter 9, *Managing Services with systemd*. 
13.1.3.1. Starting the Service

To run the httpd service, type the following at a shell prompt as root:

```
~# systemctl start httpd.service
```

If you want the service to start automatically at boot time, use the following command:

```
~# systemctl enable httpd.service
```

```
Created symlink from /etc/systemd/system/multi-user.target.wants/httpd.service to /usr/lib/systemd/system/httpd.service.
```

NOTE

If running the Apache HTTP Server as a secure server, a password may be required after the machine boots if using an encrypted private SSL key.

13.1.3.2. Stopping the Service

To stop the running httpd service, type the following at a shell prompt as root:

```
~# systemctl stop httpd.service
```

To prevent the service from starting automatically at boot time, type:

```
~# systemctl disable httpd.service
```

```
Removed symlink /etc/systemd/system/multi-user.target.wants/httpd.service.
```

13.1.3.3. Restarting the Service

There are three different ways to restart a running httpd service:

1. To restart the service completely, enter the following command as root:

```
~# systemctl restart httpd.service
```

This stops the running httpd service and immediately starts it again. Use this command after installing or removing a dynamically loaded module such as PHP.

2. To only reload the configuration, as root, type:

```
~# systemctl reload httpd.service
```

This causes the running httpd service to reload its configuration file. Any requests currently being processed will be interrupted, which may cause a client browser to display an error message or render a partial page.

3. To reload the configuration without affecting active requests, enter the following command as root:

```
~# apachectl graceful
```
This causes the running `httpd` service to reload its configuration file. Any requests currently being processed will continue to use the old configuration.

For more information on how to manage system services in Red Hat Enterprise Linux 7, see Chapter 9, *Managing Services with systemd*.

### 13.1.3.4. Verifying the Service Status

To verify that the `httpd` service is running, type the following at a shell prompt:

```
  ]# systemctl is-active httpd.service
  active
```

### 13.1.4. Editing the Configuration Files

When the `httpd` service is started, by default, it reads the configuration from locations that are listed in Table 13.1, “The `httpd` service configuration files”.

#### Table 13.1. The `httpd` service configuration files

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/etc/httpd/conf/httpd.conf</code></td>
<td>The main configuration file.</td>
</tr>
<tr>
<td><code>/etc/httpd/conf.d/</code></td>
<td>An auxiliary directory for configuration files that are included in the main configuration file.</td>
</tr>
</tbody>
</table>

Although the default configuration should be suitable for most situations, it is a good idea to become at least familiar with some of the more important configuration options. Note that for any changes to take effect, the web server has to be restarted first. See Section 13.1.3.3, “Restarting the Service” for more information on how to restart the `httpd` service.

To check the configuration for possible errors, type the following at a shell prompt:

```
  ]# apachectl configtest
  Syntax OK
```

To make the recovery from mistakes easier, it is recommended that you make a copy of the original file before editing it.

### 13.1.5. Working with Modules

Being a modular application, the `httpd` service is distributed along with a number of Dynamic Shared Objects (DSOs), which can be dynamically loaded or unloaded at runtime as necessary. On Red Hat Enterprise Linux 7, these modules are located in `/usr/lib64/httpd/modules/`.

#### 13.1.5.1. Loading a Module

To load a particular DSO module, use the `LoadModule` directive. Note that modules provided by a separate package often have their own configuration file in the `/etc/httpd/conf.d/` directory.
Example 13.1. Loading the mod_ssl DSO

```
LoadModule ssl_module modules/mod_ssl.so
```

Once you are finished, restart the web server to reload the configuration. See Section 13.1.3.3, “Restarting the Service” for more information on how to restart the `httpd` service.

### 13.1.5.2. Writing a Module

If you intend to create a new DSO module, make sure you have the `httpd-devel` package installed. To do so, enter the following command as `root`:

```
~]# yum install httpd-devel
```

This package contains the include files, the header files, and the APache eXtenSion (apxs) utility required to compile a module.

Once written, you can build the module with the following command:

```
~]# apxs -i -a -c module_name.c
```

If the build was successful, you should be able to load the module the same way as any other module that is distributed with the Apache HTTP Server.

### 13.1.6. Setting Up Virtual Hosts

The Apache HTTP Server's built in virtual hosting allows the server to provide different information based on which IP address, host name, or port is being requested.

To create a name-based virtual host, copy the example configuration file `/usr/share/doc/httpd-VERSION/httpd-vhosts.conf` into the `/etc/httpd/conf.d/` directory, and replace the `@@Port@@` and `@@ServerRoot@@` placeholder values. Customize the options according to your requirements as shown in Example 13.2, “Example virtual host configuration”.

#### Example 13.2. Example virtual host configuration

```
<VirtualHost *:80>
    ServerAdmin webmaster@penguin.example.com
    DocumentRoot "/www/docs/penguin.example.com"
    ServerName penguin.example.com
    ServerAlias www.penguin.example.com
    ErrorLog "/var/log/httpd/dummy-host.example.com-error_log"
    CustomLog "/var/log/httpd/dummy-host.example.com-access_log" common
</VirtualHost>
```

Note that `ServerName` must be a valid DNS name assigned to the machine. The `<VirtualHost>` container is highly customizable, and accepts most of the directives available within the main server configuration. Directives that are not supported within this container include `User` and `Group`, which were replaced by `SuexecUserGroup`.
NOTE

If you configure a virtual host to listen on a non-default port, make sure you update the `Listen` directive in the global settings section of the `/etc/httpd/conf/httpd.conf` file accordingly.

To activate a newly created virtual host, the web server has to be restarted first. See Section 13.1.3.3, “Restarting the Service” for more information on how to restart the `httpd` service.

13.1.7. Setting Up an SSL Server

Secure Sockets Layer (SSL) is a cryptographic protocol that allows a server and a client to communicate securely. Along with its extended and improved version called Transport Layer Security (TLS), it ensures both privacy and data integrity. The Apache HTTP Server in combination with `mod_ssl`, a module that uses the OpenSSL toolkit to provide the SSL/TLS support, is commonly referred to as the SSL server. Red Hat Enterprise Linux also supports the use of Mozilla NSS as the TLS implementation. Support for Mozilla NSS is provided by the `mod_nss` module.

Unlike an HTTP connection that can be read and possibly modified by anybody who is able to intercept it, the use of SSL/TLS over HTTP, referred to as HTTPS, prevents any inspection or modification of the transmitted content. This section provides basic information on how to enable this module in the Apache HTTP Server configuration, and guides you through the process of generating private keys and self-signed certificates.

13.1.7.1. An Overview of Certificates and Security

Secure communication is based on the use of keys. In conventional or symmetric cryptography, both ends of the transaction have the same key they can use to decode each other's transmissions. On the other hand, in public or asymmetric cryptography, two keys co-exist: a private key that is kept a secret, and a public key that is usually shared with the public. While the data encoded with the public key can only be decoded with the private key, data encoded with the private key can in turn only be decoded with the public key.

To provide secure communications using SSL, an SSL server must use a digital certificate signed by a Certificate Authority (CA). The certificate lists various attributes of the server (that is, the server host name, the name of the company, its location, etc.), and the signature produced using the CA's private key. This signature ensures that a particular certificate authority has signed the certificate, and that the certificate has not been modified in any way.

When a web browser establishes a new SSL connection, it checks the certificate provided by the web server. If the certificate does not have a signature from a trusted CA, or if the host name listed in the certificate does not match the host name used to establish the connection, it refuses to communicate with the server and usually presents a user with an appropriate error message.

By default, most web browsers are configured to trust a set of widely used certificate authorities. Because of this, an appropriate CA should be chosen when setting up a secure server, so that target users can trust the connection, otherwise they will be presented with an error message, and will have to accept the certificate manually. Since encouraging users to override certificate errors can allow an attacker to intercept the connection, you should use a trusted CA whenever possible. For more information on this, see Table 13.2, “Information about CA lists used by common web browsers”.

| Table 13.2. Information about CA lists used by common web browsers |
When setting up an SSL server, you need to generate a certificate request and a private key, and then send the certificate request, proof of the company's identity, and payment to a certificate authority. Once the CA verifies the certificate request and your identity, it will send you a signed certificate you can use with your server. Alternatively, you can create a self-signed certificate that does not contain a CA signature, and thus should be used for testing purposes only.

### 13.1.8. Enabling the mod_ssl Module

If you intend to set up an SSL or HTTPS server using mod_ssl, you cannot have another application or module, such as mod_nss configured to use the same port. Port 443 is the default port for HTTPS.

To set up an SSL server using the mod_ssl module and the OpenSSL toolkit, install the mod_ssl and openssl packages. Enter the following command as root:

```
~# yum install mod_ssl openssl
```

This will create the mod_ssl configuration file at `/etc/httpd/conf.d/ssl.conf`, which is included in the main Apache HTTP Server configuration file by default. For the module to be loaded, restart the httpd service as described in Section 13.1.3.3, “Restarting the Service”.

**IMPORTANT**

Due to the vulnerability described in [POODLE: SSLv3 vulnerability (CVE-2014-3566)](https://en.wikipedia.org/wiki/POODLE), Red Hat recommends disabling SSL and using only TLS1.1 or TLS1.2. Backwards compatibility can be achieved using TLSv1.0. Many products Red Hat supports have the ability to use SSLv2 or SSLv3 protocols, or enable them by default. However, the use of SSLv2 or SSLv3 is now strongly recommended against.

#### 13.1.8.1. Enabling and Disabling SSL and TLS in mod_ssl

To disable and enable specific versions of the SSL and TLS protocol, either do it globally by adding the `SSLProtocol` directive in the “## SSL Global Context” section of the configuration file and removing it everywhere else, or edit the default entry under “# SSL Protocol support” in all “VirtualHost” sections. If you do not specify it in the per-domain VirtualHost section then it will inherit the settings from the global section. To make sure that a protocol version is being disabled the administrator should either only specify `SSLProtocol` in the “SSL Global Context” section, or specify it in all per-domain VirtualHost sections.

**Procedure 13.1. Disable SSLv2 and SSLv3**

---

**Table 13.1.1: Web Browsers and Links**

<table>
<thead>
<tr>
<th>Web Browser</th>
<th>Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mozilla Firefox</td>
<td>Mozilla root CA list</td>
</tr>
<tr>
<td>Opera</td>
<td>Information on root certificates used by Opera</td>
</tr>
<tr>
<td>Internet Explorer</td>
<td>Information on root certificates used by Microsoft Windows</td>
</tr>
<tr>
<td>Chromium</td>
<td>Information on root certificates used by the Chromium project</td>
</tr>
</tbody>
</table>
To disable SSL version 2 and SSL version 3, which implies enabling everything except SSL version 2 and SSL version 3, in all VirtualHost sections, proceed as follows:

1. As root, open the `/etc/httpd/conf.d/ssl.conf` file and search for all instances of the `SSLProtocol` directive. By default, the configuration file contains one section that looks as follows:

   ```
   ~]# vi /etc/httpd/conf.d/ssl.conf
   # SSL Protocol support:
   # List the enable protocol levels with which clients will be able to
   # connect. Disable SSLv2 access by default:
   SSLProtocol all -SSLv2
   
   This section is within the VirtualHost section.
   ```

2. Edit the `SSLProtocol` line as follows:

   ```
   # SSL Protocol support:
   # List the enable protocol levels with which clients will be able to
   # connect. Disable SSLv2 access by default:
   SSLProtocol all -SSLv2 -SSLv3
   
   Repeat this action for all VirtualHost sections. Save and close the file.
   ```

3. Verify that all occurrences of the `SSLProtocol` directive have been changed as follows:

   ```
   ~]# grep SSLProtocol /etc/httpd/conf.d/ssl.conf
   SSLProtocol all -SSLv2 -SSLv3
   
   This step is particularly important if you have more than the one default VirtualHost section.
   ```

4. Restart the Apache daemon as follows:

   ```
   ~]# systemctl restart httpd
   
   Note that any sessions will be interrupted.
   ```

**Procedure 13.2. Disable All SSL and TLS Protocols Except TLS 1 and Up**

To disable all SSL and TLS protocol versions except TLS version 1 and higher, proceed as follows:

1. As root, open the `/etc/httpd/conf.d/ssl.conf` file and search for all instances of the `SSLProtocol` directive. By default, the file contains one section that looks as follows:

   ```
   ~]# vi /etc/httpd/conf.d/ssl.conf
   # SSL Protocol support:
   # List the enable protocol levels with which clients will be able to
   # connect. Disable SSLv2 access by default:
   SSLProtocol all -SSLv2
   
   This section is within the VirtualHost section.
   ```

2. Edit the `SSLProtocol` line as follows:

   ```
   # SSL Protocol support:
   # List the enable protocol levels with which clients will be able to
   ```
# connect. Disable SSLv2 access by default:
SSLProtocol -all +TLSv1 +TLSv1.1 +TLSv1.2

Save and close the file.

3. Verify the change as follows:

~]# grep SSLProtocol /etc/httpd/conf.d/ssl.conf
SSLProtocol -all +TLSv1 +TLSv1.1 +TLSv1.2

4. Restart the Apache daemon as follows:

~]# systemctl restart httpd

Note that any sessions will be interrupted.

Procedure 13.3. Testing the Status of SSL and TLS Protocols

To check which versions of SSL and TLS are enabled or disabled, make use of the `openssl s_client` 
- connect command. The command has the following form:

`openssl s_client -connect hostname:port -protocol`

Where `port` is the port to test and `protocol` is the protocol version to test for. To test the SSL server running locally, use `localhost` as the host name. For example, to test the default port for secure HTTPS connections, port 443 to see if SSLv3 is enabled, issue a command as follows:

1. ~]# openssl s_client -connect localhost:443 -ssl3
CONNECTED(00000003)
139809943877536:error:14094410:SSL routines:SSL3_READ_BYTES:sslv3
alert handshake failure:ss3_pkt.c:1257:SSL alert number 40
139809943877536:error:1409E0E5:SSL routines:SSL3_WRITE_BYTES:ssl
handshake failure:ss3_pkt.c:596:
output omitted
New, (NONE), Cipher is (NONE)
Secure Renegotiation IS NOT supported
Compression: NONE
Expansion: NONE
SSL-Session:
Protocol : SSLv3
output truncated

The above output indicates that the handshake failed and therefore no cipher was negotiated.

2. ~]# openssl s_client -connect localhost:443 -tls1_2
CONNECTED(00000003)
depth=0 C = --, ST = SomeState, L = SomeCity, O = SomeOrganization,
OU = SomeOrganizationalUnit, CN = localhost.localdomain,
e-mailAddress = root@localhost.localdomain
output omitted
New, TLSv1/SSLv3, Cipher is ECDHE-RSA-AES256-GCM-SHA384
Server public key is 2048 bit
Secure Renegotiation IS supported
Compression: NONE
The above output indicates that no failure of the handshake occurred and a set of ciphers was negotiated.

The `openssl s_client` command options are documented in the `s_client(1)` manual page.

For more information on the SSLv3 vulnerability and how to test for it, see the Red Hat Knowledgebase article *POODLE: SSLv3 vulnerability (CVE-2014-3566)*.

### 13.1.9. Enabling the mod_nss Module

If you intend to set up an HTTPS server using mod_nss, you cannot have the mod_ssl package installed with its default settings as mod_ssl will use port 443 by default, however this is the default HTTPS port. If at all possible, remove the package.

To remove mod_ssl, enter the following command as root:

```
~]# yum remove mod_ssl
```

**NOTE**

If `mod_ssl` is required for other purposes, modify the `/etc/httpd/conf.d/ssl.conf` file to use a port other than 443 to prevent `mod_ssl` conflicting with `mod_nss` when its port to listen on is changed to 443.

Only one module can own a port, therefore `mod_nss` and `mod_ssl` can only co-exist at the same time if they use unique ports. For this reason `mod_nss` by default uses 8443, but the default port for HTTPS is port 443. The port is specified by the `Listen` directive as well as in the VirtualHost name or address.

Everything in NSS is associated with a “token”. The software token exists in the NSS database but you can also have a physical token containing certificates. With OpenSSL, discrete certificates and private keys are held in PEM files. With NSS, these are stored in a database. Each certificate and key is associated with a token and each token can have a password protecting it. This password is optional, but if a password is used then the Apache HTTP server needs a copy of it in order to open the database without user intervention at system start.

**Procedure 13.4. Configuring mod_nss**

1. Install `mod_nss` as root:

   ```
   ~]# yum install mod_nss
   ```

   This will create the `mod_nss` configuration file at `/etc/httpd/conf.d/nss.conf`. The `/etc/httpd/conf.d/` directory is included in the main Apache HTTP Server configuration file by default. For the module to be loaded, restart the httpd service as described in *Section 13.1.3.3, “Restarting the Service”*.  

---

**Expansion: NONE**

**SSL-Session:**

- **Protocol**: TLSv1.2
- **output truncated**
2. As root, open the /etc/httpd/conf.d/nss.conf file and search for all instances of the Listen directive.

   Edit the Listen 8443 line as follows:

   ```
   Listen 443
   ```

   Port 443 is the default port for HTTPS.

3. Edit the default VirtualHost _default_:8443 line as follows:

   ```
   VirtualHost _default_:443
   ```

   Edit any other non-default virtual host sections if they exist. Save and close the file.

4. Mozilla NSS stores certificates in a server certificate database indicated by the NSSCertificateDatabase directive in the /etc/httpd/conf.d/nss.conf file. By default the path is set to /etc/httpd/alias, the NSS database created during installation.

   To view the default NSS database, issue a command as follows:

   ```
   ~$]# certutil -L -d /etc/httpd/alias
   ```

<table>
<thead>
<tr>
<th>Certificate Nickname</th>
<th>Trust Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL,S/MIME,JAR/XPI</td>
<td></td>
</tr>
<tr>
<td>cacert</td>
<td></td>
</tr>
<tr>
<td>CTu,Cu,Cu</td>
<td></td>
</tr>
<tr>
<td>Server-Cert</td>
<td></td>
</tr>
<tr>
<td>u,u,u</td>
<td></td>
</tr>
<tr>
<td>alpha</td>
<td></td>
</tr>
<tr>
<td>u,pu,u</td>
<td></td>
</tr>
</tbody>
</table>

   In the above command output, Server-Cert is the default NSSNickname. The -L option lists all the certificates, or displays information about a named certificate, in a certificate database. The -d option specifies the database directory containing the certificate and key database files. See the `certutil(1)` man page for more command line options.

5. To configure mod_nss to use another database, edit the NSSCertificateDatabase line in the /etc/httpd/conf.d/nss.conf file. The default file has the following lines within the VirtualHost section.

   ```
   #   Server Certificate Database:
   #   The NSS security database directory that holds the certificates and keys. The database consists of 3 files: cert8.db, key3.db and secmod.db.
   #   Provide the directory that these files exist.
   NSSCertificateDatabase /etc/httpd/alias
   ```

   In the above command output, alias is the default NSS database directory, /etc/httpd/alias/. 

6. To apply a password to the default NSS certificate database, use the following command as root:

```
~# certutil -W -d /etc/httpd/alias
Enter Password or Pin for "NSS Certificate DB":
Enter a password which will be used to encrypt your keys.
The password should be at least 8 characters long,
and should contain at least one non-alphabetic character.

Enter new password:
Re-enter password:
Password changed successfully.
```

7. Before deploying the HTTPS server, create a new certificate database using a certificate signed by a certificate authority (CA).

**Example 13.3. Adding a Certificate to the Mozilla NSS database**

The `certutil` command is used to add a CA certificate to the NSS database files:

```
certutil -d /etc/httpd/nss-db-directory/ -A -n "CA_certificate" -t CT,, -a -i certificate.pem
```

The above command adds a CA certificate stored in a PEM-formatted file named `certificate.pem`. The `-d` option specifies the NSS database directory containing the certificate and key database files, the `-n` option sets a name for the certificate, `-t CT,,` means that the certificate is trusted to be used in TLS clients and servers. The `-A` option adds an existing certificate to a certificate database. If the database does not exist it will be created. The `-a` option allows the use of ASCII format for input or output, and the `-i` option passes the `certificate.pem` input file to the command.

See the `certutil(1)` man page for more command line options.

8. The NSS database should be password protected to safeguard the private key.

**Example 13.4. Setting a Password for a Mozilla NSS database**

The `certutil` tool can be used set a password for an NSS database as follows:

```
certutil -W -d /etc/httpd/nss-db-directory/
```

For example, for the default database, issue a command as `root` as follows:

```
~# certutil -W -d /etc/httpd/alias
Enter Password or Pin for "NSS Certificate DB":
Enter a password which will be used to encrypt your keys.
The password should be at least 8 characters long,
and should contain at least one non-alphabetic character.

Enter new password:
Re-enter password:
Password changed successfully.
```
9. Configure `mod_nss` to use the NSS internal software token by changing the line with the `NSSPassPhraseDialog` directive as follows:

```
[#] vi /etc/httpd/conf.d/nss.conf
NSSPassPhraseDialog file:/etc/httpd/password.conf
```

This is to avoid manual password entry on system start. The software token exists in the NSS database but you can also have a physical token containing your certificates.

10. If the SSL Server Certificate contained in the NSS database is an RSA certificate, make certain that the `NSSNickname` parameter is uncommented and matches the nickname displayed in step 4 above:

```
[#] vi /etc/httpd/conf.d/nss.conf
NSSNickname Server-Cert
```

If the SSL Server Certificate contained in the NSS database is an ECC certificate, make certain that the `NSSECCNickname` parameter is uncommented and matches the nickname displayed in step 4 above:

```
[#] vi /etc/httpd/conf.d/nss.conf
NSSECCNickname Server-Cert
```

Make certain that the `NSSCertificateDatabase` parameter is uncommented and points to the NSS database directory displayed in step 4 or configured in step 5 above:

```
[#] vi /etc/httpd/conf.d/nss.conf
NSSCertificateDatabase /etc/httpd/alias
```

Replace `/etc/httpd/alias` with the path to the certificate database to be used.

11. Create the `/etc/httpd/password.conf` file as root:

```
[#] vi /etc/httpd/password.conf
```

Add a line with the following form:

```
internal:password
```

Replacing `password` with the password that was applied to the NSS security databases in step 6 above.

12. Apply the appropriate ownership and permissions to the `/etc/httpd/password.conf` file:

```
[#] chgrp apache /etc/httpd/password.conf
[#] chmod 640 /etc/httpd/password.conf
```

```
-rw-r----- 1 root apache 10 Dec 4 17:13 /etc/httpd/password.conf
```

13. To configure `mod_nss` to use the NSS the software token in `/etc/httpd/password.conf`, edit `/etc/httpd/conf.d/nss.conf` as follows:
14. Restart the Apache server for the changes to take effect as described in Section 13.1.3.3, “Restarting the Service”

**IMPORTANT**

Due to the vulnerability described in [POODLE: SSLv3 vulnerability (CVE-2014-3566)](http://example.com), Red Hat recommends disabling SSL and using only TLSv1.1 or TLSv1.2. Backwards compatibility can be achieved using TLSv1.0. Many products Red Hat supports have the ability to use SSLv2 or SSLv3 protocols, or enable them by default. However, the use of SSLv2 or SSLv3 is now strongly recommended against.

### 13.1.9.1. Enabling and Disabling SSL and TLS in mod_nss

To disable and enable specific versions of the SSL and TLS protocol, either do it globally by adding the ` NSSProtocol` directive in the “### SSL Global Context” section of the configuration file and removing it everywhere else, or edit the default entry under “# SSL Protocol” in all “VirtualHost” sections. If you do not specify it in the per-domain VirtualHost section then it will inherit the settings from the global section. To make sure that a protocol version is being disabled the administrator should either only specify ` NSSProtocol` in the “SSL Global Context” section, or specify it in all per-domain VirtualHost sections.

#### Procedure 13.5. Disable All SSL and TLS Protocols Except TLS 1 and Up in mod_nss

To disable all SSL and TLS protocol versions except TLS version 1 and higher, proceed as follows:

1. As root, open the `/etc/httpd/conf.d/nss.conf` file and search for all instances of the ` NSSProtocol` directive. By default, the configuration file contains one section that looks as follows:

   ```
   ~]# vi /etc/httpd/conf.d/nss.conf
   #   SSL Protocol:
   output omitted
   #   Since all protocol ranges are completely inclusive, and no
   #   protocol in the
   #   middle of a range may be excluded, the entry "NSSProtocol
   #   SSLv3,TLSv1.1"
   #   is identical to the entry "NSSProtocol SSLv3,TLSv1.0,TLSv1.1".
   NSSProtocol SSLv3,TLSv1.0,TLSv1.1
   This section is within the VirtualHost section.
   ```

2. Edit the ` NSSProtocol` line as follows:

   ```
   #   SSL Protocol:
   NSSProtocol TLSv1.0,TLSv1.1
   ```

   Repeat this action for all VirtualHost sections.

3. Edit the `Listen 8443` line as follows:

   ```
   Listen 443
   ```
4. Edit the default `VirtualHost _default_:8443` line as follows:

```
VirtualHost _default_:443
```

Edit any other non-default virtual host sections if they exist. Save and close the file.

5. Verify that all occurrences of the `NSSProtocol` directive have been changed as follows:

```
~]$ grep NSSProtocol /etc/httpd/conf.d/nss.conf
# middle of a range may be excluded, the entry "NSSProtocol SSLv3,TLSv1.1"
# is identical to the entry "NSSProtocol SSLv3,TLSv1.0,TLSv1.1".
NSSProtocol TLSv1.0,TLSv1.1
```

This step is particularly important if you have more than one `VirtualHost` section.

6. Restart the Apache daemon as follows:

```
~]$ service httpd restart
```

Note that any sessions will be interrupted.

**Procedure 13.6. Testing the Status of SSL and TLS Protocols in mod_nss**

To check which versions of SSL and TLS are enabled or disabled in `mod_nss`, make use of the `openssl s_client -connect` command. Install the `openssl` package as `root`:

```
~]$ yum install openssl
```

The `openssl s_client -connect` command has the following form:

```
openssl s_client -connect hostname:port -protocol
```

Where `port` is the port to test and `protocol` is the protocol version to test for. To test the SSL server running locally, use `localhost` as the host name. For example, to test the default port for secure HTTPS connections, port `443` to see if SSLv3 is enabled, issue a command as follows:

```
1. ~]$ openssl s_client -connect localhost:443 -ssl3
CONNECTED(00000003) 3077773036:error:1408F10B:SSL routines:SSL3_GET_RECORD:wrong version number:s3_pkt.c:337:
output omitted
New, (NONE), Cipher is (NONE)
Secure Renegotiation IS NOT supported
Compression: NONE
Expansion: NONE
SSL-Session:
    Protocol : SSLv3
output truncated
```

The above output indicates that the handshake failed and therefore no cipher was negotiated.

```
2. ~]$ openssl s_client -connect localhost:443 -tls1
```
The above output indicates that no failure of the handshake occurred and a set of ciphers was negotiated.

The `openssl s_client` command options are documented in the `s_client(1)` manual page.

For more information on the SSLv3 vulnerability and how to test for it, see the Red Hat Knowledgebase article POODLE: SSLv3 vulnerability (CVE-2014-3566).

### 13.1.10. Using an Existing Key and Certificate

If you have a previously created key and certificate, you can configure the SSL server to use these files instead of generating new ones. There are only two situations where this is not possible:

1. **You are changing the IP address or domain name.**

   Certificates are issued for a particular IP address and domain name pair. If one of these values changes, the certificate becomes invalid.

2. **You have a certificate from VeriSign, and you are changing the server software.**

   VeriSign, a widely used certificate authority, issues certificates for a particular software product, IP address, and domain name. Changing the software product renders the certificate invalid.

In either of the above cases, you will need to obtain a new certificate. For more information on this topic, see Section 13.1.11, “Generating a New Key and Certificate”.

If you want to use an existing key and certificate, move the relevant files to the `/etc/pki/tls/private/` and `/etc/pki/tls/certs/` directories respectively. You can do so by issuing the following commands as `root`:

```
~]# mv key_file.key /etc/pki/tls/private/hostname.key
~]# mv certificate.crt /etc/pki/tls/certs/hostname.crt
```

Then add the following lines to the `/etc/httpd/conf.d/ssl.conf` configuration file:

```
SSLCertificateFile /etc/pki/tls/certs/hostname.crt
SSLCertificateKeyFile /etc/pki/tls/private/hostname.key
```

To load the updated configuration, restart the `httpd` service as described in Section 13.1.3.3, “Restarting the Service”.

**Example 13.5. Using a key and certificate from the Red Hat Secure Web Server**
13.1.11. Generating a New Key and Certificate

In order to generate a new key and certificate pair, the crypto-utils package must be installed on the system. To install it, enter the following command as root:

```bash
$ yum install crypto-utils
```

This package provides a set of tools to generate and manage SSL certificates and private keys, and includes genkey, the Red Hat Keypair Generation utility that will guide you through the key generation process.

**IMPORTANT**

If the server already has a valid certificate and you are replacing it with a new one, specify a different serial number. This ensures that client browsers are notified of this change, update to this new certificate as expected, and do not fail to access the page. To create a new certificate with a custom serial number, as root, use the following command instead of genkey:

```bash
$ openssl req -x509 -new -set_serial number -key hostname.key -out hostname.crt
```

**NOTE**

If there already is a key file for a particular host name in your system, genkey will refuse to start. In this case, remove the existing file using the following command as root:

```bash
$ rm /etc/pki/tls/private/hostname.key
```

To run the utility enter the genkey command as root, followed by the appropriate host name (for example, penguin.example.com):

```bash
$ genkey hostname
```

To complete the key and certificate creation, take the following steps:

1. Review the target locations in which the key and certificate will be stored.
Figure 13.1. Running the genkey utility

Use the Tab key to select the Next button, and press Enter to proceed to the next screen.

2. Using the up and down arrow keys, select a suitable key size. Note that while a larger key increases the security, it also increases the response time of your server. The NIST recommends using **2048 bits**. See *NIST Special Publication 800-131A*.

Figure 13.2. Selecting the key size

Once finished, use the Tab key to select the Next button, and press Enter to initiate the random bits generation process. Depending on the selected key size, this may take some time.

3. Decide whether you want to send a certificate request to a certificate authority.
Figure 13.3. Generating a certificate request

Use the Tab key to select Yes to compose a certificate request, or No to generate a self-signed certificate. Then press Enter to confirm your choice.

4. Using the Spacebar key, enable ([*]) or disable ( [ ]) the encryption of the private key.

Figure 13.4. Encrypting the private key

Use the Tab key to select the Next button, and press Enter to proceed to the next screen.

5. If you have enabled the private key encryption, enter an adequate passphrase. Note that for security reasons, it is not displayed as you type, and it must be at least five characters long.
Use the Tab key to select the Next button, and press Enter to proceed to the next screen.

**IMPORTANT**

Entering the correct passphrase is required in order for the server to start. If you lose it, you will need to generate a new key and certificate.

6. Customize the certificate details.

Figure 13.6. Specifying certificate information
Use the Tab key to select the Next button, and press Enter to finish the key generation.

7. If you have previously enabled the certificate request generation, you will be prompted to send it to a certificate authority.

![Certificate Request Instructions]

Press Enter to return to a shell prompt.

Once generated, add the key and certificate locations to the /etc/httpd/conf.d/ssl.conf configuration file:

- SSLCertificateFile /etc/pki/tls/certs/hostname.crt
- SSLCertificateKeyFile /etc/pki/tls/private/hostname.key

Finally, restart the httpd service as described in Section 13.1.3.3, “Restarting the Service”, so that the updated configuration is loaded.

13.1.12. Configure the Firewall for HTTP and HTTPS Using the Command Line

Red Hat Enterprise Linux does not allow HTTP and HTTPS traffic by default. To enable the system to act as a web server, make use of firewalld's supported services to enable HTTP and HTTPS traffic to pass through the firewall as required.

To enable HTTP using the command line, issue the following command as root:

```bash
~ ] # firewall-cmd --add-service http
success
```

To enable HTTPS using the command line, issue the following command as root:

```bash
~ ] # firewall-cmd --add-service https
success
```
Note that these changes will not persist after the next system start. To make permanent changes to the firewall, repeat the commands adding the \texttt{-p permanent} option.

To check what services the firewall is configured to allow, using the command line, issue the following command as \texttt{root}:

\begin{verbatim}
   ~# firewall-cmd --list-all
   public (default, active)
     interfaces: em1
     sources:
     services: dhcpv6-client ssh

   output truncated
\end{verbatim}

In this example taken from a default installation, the firewall is enabled but \texttt{HTTP} and \texttt{HTTPS} have not been allowed to pass through.

Once the \texttt{HTTP} and \texttt{HTTPS} firewall services are enabled, the \texttt{services} line will appear similar to the following:

\begin{verbatim}
   services: dhcpv6-client http https ssh
\end{verbatim}

For more information on enabling firewall services, or opening and closing ports with \texttt{firewalld}, see the \textit{Red Hat Enterprise Linux 7 Security Guide}.

13.1.13. Additional Resources

To learn more about the Apache HTTP Server, see the following resources.

\textbf{Installed Documentation}

- \texttt{httpd(8)} – The manual page for the \texttt{httpd} service containing the complete list of its command-line options.
- \texttt{genkey(1)} – The manual page for \texttt{genkey} utility, provided by the \texttt{crypto-utils} package.
- \texttt{apachectl(8)} – The manual page for the Apache HTTP Server Control Interface.

\textbf{Installable Documentation}

- \url{http://localhost/manual/} – The official documentation for the Apache HTTP Server with the full description of its directives and available modules. Note that in order to access this documentation, you must have the \texttt{httpd-manual} package installed, and the web server must be running.

Before accessing the documentation, issue the following commands as \texttt{root}:

\begin{verbatim}
   ~# yum install httpd-manual
   ~# apachectl graceful
\end{verbatim}

\textbf{Online Documentation}

- \url{http://httpd.apache.org/} – The official website for the Apache HTTP Server with
documentation on all the directives and default modules.

- [http://www.openssl.org/](http://www.openssl.org/) – The OpenSSL home page containing further documentation, frequently asked questions, links to the mailing lists, and other useful resources.
CHAPTER 14. MAIL SERVERS

Red Hat Enterprise Linux offers many advanced applications to serve and access email. This chapter describes modern email protocols in use today, and some of the programs designed to send and receive email.

14.1. EMAIL PROTOCOLS

Today, email is delivered using a client/server architecture. An email message is created using a mail client program. This program then sends the message to a server. The server then forwards the message to the recipient's email server, where the message is then supplied to the recipient's email client.

To enable this process, a variety of standard network protocols allow different machines, often running different operating systems and using different email programs, to send and receive email.

The following protocols discussed are the most commonly used in the transfer of email.

14.1.1. Mail Transport Protocols

Mail delivery from a client application to the server, and from an originating server to the destination server, is handled by the Simple Mail Transfer Protocol (SMTP).

14.1.1.1. SMTP

The primary purpose of SMTP is to transfer email between mail servers. However, it is critical for email clients as well. To send email, the client sends the message to an outgoing mail server, which in turn contacts the destination mail server for delivery. For this reason, it is necessary to specify an SMTP server when configuring an email client.

Under Red Hat Enterprise Linux, a user can configure an SMTP server on the local machine to handle mail delivery. However, it is also possible to configure remote SMTP servers for outgoing mail.

One important point to make about the SMTP protocol is that it does not require authentication. This allows anyone on the Internet to send email to anyone else or even to large groups of people. It is this characteristic of SMTP that makes junk email or spam possible. Imposing relay restrictions limits random users on the Internet from sending email through your SMTP server, to other servers on the internet. Servers that do not impose such restrictions are called open relay servers.

Red Hat Enterprise Linux 7 provides the Postfix and Sendmail SMTP programs.

14.1.2. Mail Access Protocols

There are two primary protocols used by email client applications to retrieve email from mail servers: the Post Office Protocol (POP) and the Internet Message Access Protocol (IMAP).

14.1.2.1. POP

The default POP server under Red Hat Enterprise Linux is Dovecot and is provided by the dovecot package.
NOTE

In order to use **Dovecot**, first ensure the `dovecot` package is installed on your system by running, as `root`:

```bash
~]# yum install dovecot
```

For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

When using a **POP** server, email messages are downloaded by email client applications. By default, most **POP** email clients are automatically configured to delete the message on the email server after it has been successfully transferred, however this setting usually can be changed.

**POP** is fully compatible with important Internet messaging standards, such as *Multipurpose Internet Mail Extensions (MIME)*, which allow for email attachments.

**POP** works best for users who have one system on which to read email. It also works well for users who do not have a persistent connection to the Internet or the network containing the mail server. Unfortunately for those with slow network connections, **POP** requires client programs upon authentication to download the entire content of each message. This can take a long time if any messages have large attachments.

The most current version of the standard **POP** protocol is **POP3**.

There are, however, a variety of lesser-used **POP** protocol variants:

- **APOP** — **POP3** with MD5 authentication. An encoded hash of the user's password is sent from the email client to the server rather than sending an unencrypted password.

- **KPOP** — **POP3** with Kerberos authentication.

- **RPOP** — **POP3** with RPOP authentication. This uses a per-user ID, similar to a password, to authenticate POP requests. However, this ID is not encrypted, so **RPOP** is no more secure than standard **POP**.

For added security, it is possible to use *Secure Socket Layer (SSL)* encryption for client authentication and data transfer sessions. This can be enabled by using the `pop3s` service, or by using the `stunnel` application. For more information on securing email communication, see Section 14.5.1, “Securing Communication”.

### 14.1.2.2. IMAP

The default **IMAP** server under Red Hat Enterprise Linux is **Dovecot** and is provided by the `dovecot` package. See Section 14.1.2.1, “POP” for information on how to install **Dovecot**.

When using an **IMAP** mail server, email messages remain on the server where users can read or delete them. **IMAP** also allows client applications to create, rename, or delete mail directories on the server to organize and store email.

**IMAP** is particularly useful for users who access their email using multiple machines. The protocol is also convenient for users connecting to the mail server via a slow connection, because only the email header information is downloaded for messages until opened, saving bandwidth. The user also has the ability to delete messages without viewing or downloading them.
For convenience, **IMAP** client applications are capable of caching copies of messages locally, so the user can browse previously read messages when not directly connected to the **IMAP** server.

**IMAP**, like **POP**, is fully compatible with important Internet messaging standards, such as MIME, which allow for email attachments.

For added security, it is possible to use SSL encryption for client authentication and data transfer sessions. This can be enabled by using the `imaps` service, or by using the `stunnel` program. For more information on securing email communication, see Section 14.5.1, “Securing Communication”.

Other free, as well as commercial, **IMAP** clients and servers are available, many of which extend the **IMAP** protocol and provide additional functionality.

### 14.1.2.3. Dovecot

The `imap-login` and `pop3-login` processes which implement the **IMAP** and **POP3** protocols are spawned by the master `dovecot` daemon included in the `dovecot` package. The use of **IMAP** and **POP** is configured through the `/etc/dovecot/dovecot.conf` configuration file; by default, `dovecot` runs **IMAP** and **POP3** together with their secure versions using **SSL**. To configure `dovecot` to use **POP**, complete the following steps:

1. Edit the `/etc/dovecot/dovecot.conf` configuration file to make sure the `protocols` variable is uncommented (remove the hash sign (`#`) at the beginning of the line) and contains the `pop3` argument. For example:

   ```
   protocols = imap pop3 lmtp
   ```

   When the `protocols` variable is left commented out, `dovecot` will use the default values as described above.

2. Make the change operational for the current session by running the following command as `root`:

   ```
   ~]$ systemctl restart dovecot
   ```

3. Make the change operational after the next reboot by running the command:

   ```
   ~]$ systemctl enable dovecot
   ```

   Created symlink from `/etc/systemd/system/multi-user.target.wants/dovecot.service` to `/usr/lib/systemd/system/dovecot.service`.

   **NOTE**

   Please note that `dovecot` only reports that it started the **IMAP** server, but also starts the **POP3** server.

Unlike **SMTP**, both **IMAP** and **POP3** require connecting clients to authenticate using a user name and password. By default, passwords for both protocols are passed over the network unencrypted.

To configure **SSL** on `dovecot`:

- Edit the `/etc/dovecot/conf.d/10-ssl.conf` configuration to make sure the
ssl_protocols variable is uncommented and contains the `!SSLv2 !SSLv3` arguments:

```
ssl_protocols = !SSLv2 !SSLv3
```

These values ensure that dovecot avoids SSL versions 2 and also 3, which are both known to be insecure. This is due to the vulnerability described in [POODLE: SSLv3 vulnerability (CVE-2014-3566)](http://www.dovecot.org). See [Resolution for POODLE SSL 3.0 vulnerability (CVE-2014-3566) in Postfix and Dovecot](http://www.dovecot.org) for details.

- Edit the `/etc/pki/dovecot/dovecot-openssl.cnf` configuration file as you prefer. However, in a typical installation, this file does not require modification.

- Rename, move or delete the files `/etc/pki/dovecot/certs/dovecot.pem` and `/etc/pki/dovecot/private/dovecot.pem`.

- Execute the `/usr/libexec/dovecot/mkcert.sh` script which creates the `dovecot` self signed certificates. These certificates are copied in the `/etc/pki/dovecot/certs` and `/etc/pki/dovecot/private` directories. To implement the changes, restart `dovecot` by issuing the following command as `root`:

```
~]# systemctl restart dovecot
```

More details on `dovecot` can be found online at [http://www.dovecot.org](http://www.dovecot.org).

### 14.2. EMAIL PROGRAM CLASSIFICATIONS

In general, all email applications fall into at least one of three classifications. Each classification plays a specific role in the process of moving and managing email messages. While most users are only aware of the specific email program they use to receive and send messages, each one is important for ensuring that email arrives at the correct destination.

#### 14.2.1. Mail Transport Agent

A Mail Transport Agent (MTA) transports email messages between hosts using SMTP. A message may involve several MTAs as it moves to its intended destination.

While the delivery of messages between machines may seem rather straightforward, the entire process of deciding if a particular MTA can or should accept a message for delivery is quite complicated. In addition, due to problems from spam, use of a particular MTA is usually restricted by the MTA's configuration or the access configuration for the network on which the MTA resides.

Many modern email client programs can act as an MTA when sending email. However, this action should not be confused with the role of a true MTA. The sole reason email client programs are capable of sending email like an MTA is because the host running the application does not have its own MTA. This is particularly true for email client programs on non-UNIX-based operating systems. However, these client programs only send outbound messages to an MTA they are authorized to use and do not directly deliver the message to the intended recipient's email server.

Since Red Hat Enterprise Linux offers two MTAs, Postfix and Sendmail, email client programs are often not required to act as an MTA. Red Hat Enterprise Linux also includes a special purpose MTA called Fetchmail.

For more information on Postfix, Sendmail, and Fetchmail, see Section 14.3, “Mail Transport Agents”.
14.2.2. Mail Delivery Agent

A Mail Delivery Agent (MDA) is invoked by the MTA to file incoming email in the proper user's mailbox. In many cases, the MDA is actually a Local Delivery Agent (LDA), such as mail or Procmail.

Any program that actually handles a message for delivery to the point where it can be read by an email client application can be considered an MDA. For this reason, some MTAs (such as Sendmail and Postfix) can fill the role of an MDA when they append new email messages to a local user's mail spool file. In general, MDAs do not transport messages between systems nor do they provide a user interface; MDAs distribute and sort messages on the local machine for an email client application to access.

14.2.3. Mail User Agent

A Mail User Agent (MUA) is synonymous with an email client application. An MUA is a program that, at a minimum, allows a user to read and compose email messages. Many MUAs are capable of retrieving messages via the POP or IMAP protocols, setting up mailboxes to store messages, and sending outbound messages to an MTA.

MUAs may be graphical, such as Evolution, or have simple text-based interfaces, such as Mutt.

14.3. MAIL TRANSPORT AGENTS

Red Hat Enterprise Linux 7 offers two primary MTAs: Postfix and Sendmail. Postfix is configured as the default MTA and Sendmail is considered deprecated. If required to switch the default MTA to Sendmail, you can either uninstall Postfix or use the following command as root to switch to Sendmail:

```
~# alternatives --config mta
```

You can also use the following command to enable the desired service:

```
~# systemctl enable service
```

Similarly, to disable the service, type the following at a shell prompt:

```
~# systemctl disable service
```

For more information on how to manage system services in Red Hat Enterprise Linux 7, see Chapter 9, Managing Services with systemd.

14.3.1. Postfix

Originally developed at IBM by security expert and programmer Wietse Venema, Postfix is a Sendmail-compatible MTA that is designed to be secure, fast, and easy to configure.

To improve security, Postfix uses a modular design, where small processes with limited privileges are launched by a master daemon. The smaller, less privileged processes perform very specific tasks related to the various stages of mail delivery and run in a changed root environment to limit the effects of attacks.

Configuring Postfix to accept network connections from hosts other than the local computer takes only a few minor changes in its configuration file. Yet for those with more complex needs, Postfix provides a variety of configuration options, as well as third party add-ons that make it a very versatile and full-featured MTA.
The configuration files for Postfix are human readable and support upward of 250 directives. Unlike Sendmail, no macro processing is required for changes to take effect and the majority of the most commonly used options are described in the heavily commented files.

14.3.1.1. The Default Postfix Installation

The Postfix executable is `postfix`. This daemon launches all related processes needed to handle mail delivery.

Postfix stores its configuration files in the `/etc/postfix/` directory. The following is a list of the more commonly used files:

- `access` — Used for access control, this file specifies which hosts are allowed to connect to Postfix.
- `main.cf` — The global Postfix configuration file. The majority of configuration options are specified in this file.
- `master.cf` — Specifies how Postfix interacts with various processes to accomplish mail delivery.
- `transport` — Maps email addresses to relay hosts.

The `aliases` file can be found in the `/etc` directory. This file is shared between Postfix and Sendmail. It is a configurable list required by the mail protocol that describes user ID aliases.

**IMPORTANT**

The default `/etc/postfix/main.cf` file does not allow Postfix to accept network connections from a host other than the local computer. For instructions on configuring Postfix as a server for other clients, see Section 14.3.1.3, “Basic Postfix Configuration”.

Restart the `postfix` service after changing any options in the configuration files under the `/etc/postfix/` directory in order for those changes to take effect. To do so, run the following command as root:

```
~]# systemctl restart postfix
```

14.3.1.2. Upgrading From a Previous Release

The following settings in Red Hat Enterprise Linux 7 are different to previous releases:

- `disable_vrfy_command = no` — This is disabled by default, which is different to the default for Sendmail. If changed to `yes` it can prevent certain email address harvesting methods.

- `allow_percent_hack = yes` — This is enabled by default. It allows removing `%` characters in email addresses. The percent hack is an old workaround that allowed sender-controlled routing of email messages. DNS and mail routing are now much more reliable, but Postfix continues to support the hack. To turn off percent rewriting, set `allow_percent_hack` to `no`.

- `smtpd_helo_required = no` — This is disabled by default, as it is in Sendmail, because it can prevent some applications from sending mail. It can be changed to `yes` to require clients to send the HELO or EHLO commands before attempting to send the MAIL, FROM, or ETRN commands.
14.3.1.3. Basic Postfix Configuration

By default, Postfix does not accept network connections from any host other than the local host. Perform the following steps as root to enable mail delivery for other hosts on the network:

- Edit the `/etc/postfix/main.cf` file with a text editor, such as `vi`.
- Uncomment the `mydomain` line by removing the hash sign (`#`), and replace `domain.tld` with the domain the mail server is servicing, such as `example.com`.
- Uncomment the `myorigin = $mydomain` line.
- Uncomment the `myhostname` line, and replace `host.domain.tld` with the host name for the machine.
- Uncomment the `mydestination = $myhostname, localhost.$mydomain` line.
- Uncomment the `mynetworks` line, and replace `168.100.189.0/28` with a valid network setting for hosts that can connect to the server.
- Uncomment the `inet_interfaces = all` line.
- Comment the `inet_interfaces = localhost` line.
- Restart the `postfix` service.

Once these steps are complete, the host accepts outside emails for delivery.

Postfix has a large assortment of configuration options. One of the best ways to learn how to configure Postfix is to read the comments within the `/etc/postfix/main.cf` configuration file. Additional resources including information about Postfix configuration, SpamAssassin integration, or detailed descriptions of the `/etc/postfix/main.cf` parameters are available online at http://www.postfix.org/.

**IMPORTANT**

Due to the vulnerability described in Poodle: SSLv3 vulnerability (CVE-2014-3566), Red Hat recommends disabling SSL and using only TLSv1.1 or TLSv1.2. See Resolution for Poodle SSL 3.0 vulnerability (CVE-2014-3566) in Postfix and Dovecot for details.

14.3.1.4. Using Postfix with LDAP

Postfix can use an LDAP directory as a source for various lookup tables (e.g.: aliases, virtual, canonical, etc.). This allows LDAP to store hierarchical user information and Postfix to only be given the result of LDAP queries when needed. By not storing this information locally, administrators can easily maintain it.

14.3.1.4.1. The `/etc/aliases` lookup example

The following is a basic example for using LDAP to look up the `/etc/aliases` file. Make sure your `/etc/postfix/main.cf` file contains the following:

```
alias_maps = hash:/etc/aliases, ldap:/etc/postfix/ldap-aliases.cf
```
Create a `/etc/postfix/ldap-aliases.cf` file if you do not have one already and make sure it contains the following:

```
server_host = ldap.example.com
search_base = dc=example, dc=com
```

where `ldap.example.com`, `example`, and `com` are parameters that need to be replaced with specification of an existing available LDAP server.

**NOTE**

The `/etc/postfix/ldap-aliases.cf` file can specify various parameters, including parameters that enable LDAP SSL and STARTTLS. For more information, see the `ldap_table(5)` man page.

For more information on LDAP, see OpenLDAP in the System-Level Authentication Guide.

### 14.3.2. Sendmail

Sendmail's core purpose, like other MTAs, is to safely transfer email among hosts, usually using the SMTP protocol. Note that Sendmail is considered deprecated and users are encouraged to use Postfix when possible. See Section 14.3.1, “Postfix” for more information.

#### 14.3.2.1. Purpose and Limitations

It is important to be aware of what Sendmail is and what it can do, as opposed to what it is not. In these days of monolithic applications that fulfill multiple roles, Sendmail may seem like the only application needed to run an email server within an organization. Technically, this is true, as Sendmail can spool mail to each users' directory and deliver outbound mail for users. However, most users actually require much more than simple email delivery. Users usually want to interact with their email using an MUA, that uses POP or IMAP, to download their messages to their local machine. Or, they may prefer a Web interface to gain access to their mailbox. These other applications can work in conjunction with Sendmail, but they actually exist for different reasons and can operate separately from one another.

It is beyond the scope of this section to go into all that Sendmail should or could be configured to do. With literally hundreds of different options and rule sets, entire volumes have been dedicated to helping explain everything that can be done and how to fix things that go wrong. See the Section 14.6, “Additional Resources” for a list of Sendmail resources.

This section reviews the files installed with Sendmail by default and reviews basic configuration changes, including how to stop unwanted email (spam) and how to extend Sendmail with the Lightweight Directory Access Protocol (LDAP).

#### 14.3.2.2. The Default Sendmail Installation

In order to use Sendmail, first ensure the `sendmail` package is installed on your system by running, as `root`:

```
~]$ yum install sendmail
```

In order to configure Sendmail, ensure the `sendmail-cf` package is installed on your system by running, as `root`:
For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

Before using Sendmail, the default MTA has to be switched from Postfix. For more information how to switch the default MTA refer to Section 14.3, “Mail Transport Agents”.

The Sendmail executable is `sendmail`.

Sendmail's lengthy and detailed configuration file is `/etc/mail/sendmail.cf`. Avoid editing the `sendmail.cf` file directly. To make configuration changes to Sendmail, edit the `/etc/mail/sendmail.mc` file, back up the original `/etc/mail/sendmail.cf` file, and use the following alternatives to generate a new configuration file:

- Use the included makefile in `/etc/mail/` to create a new `/etc/mail/sendmail.cf` configuration file:

  ```
  ~]# make all -C /etc/mail/
  ```

  All other generated files in `/etc/mail` (db files) will be regenerated if needed. The old `makemap` commands are still usable. The make command is automatically used whenever you start or restart the `sendmail` service.

More information on configuring Sendmail can be found in Section 14.3.2.3, “Common Sendmail Configuration Changes”.

Various Sendmail configuration files are installed in the `/etc/mail/` directory including:

- `access` — Specifies which systems can use Sendmail for outbound email.
- `domaintable` — Specifies domain name mapping.
- `local-host-names` — Specifies aliases for the host.
- `mailertable` — Specifies instructions that override routing for particular domains.
- `virtusertable` — Specifies a domain-specific form of aliasing, allowing multiple virtual domains to be hosted on one machine.

Several of the configuration files in the `/etc/mail/` directory, such as `access`, `domaintable`, `mailertable` and `virtusertable`, must actually store their information in database files before Sendmail can use any configuration changes. To include any changes made to these configurations in their database files, run the following commands, as root:

  ```
  ~]# cd /etc/mail/
  ~]# make all
  ```

  This will update `virtusertable.db`, `access.db`, `domaintable.db`, `mailertable.db`, `sendmail.cf`, and `submit.cf`.

To update all the database files listed above and to update a custom database file, use a command in the following format:

  ```
  make name.db all
  ```
where `name` represents the name of the custom database file to be updated.

To update a single database, use a command in the following format:

```
make name.db
```

where `name.db` represents the name of the database file to be updated.

You may also restart the `sendmail` service for the changes to take effect by running:

```
~$ systemctl restart sendmail
```

For example, to have all emails addressed to the `example.com` domain delivered to `bob@other-example.com`, add the following line to the `virtusertable` file:

```
@example.com bob@other-example.com
```

To finalize the change, the `virtusertable.db` file must be updated:

```
~$ make virtusertable.db all
```

Using the `all` option will result in the `virtusertable.db` and `access.db` being updated at the same time.

### 14.3.2.3. Common Sendmail Configuration Changes

When altering the Sendmail configuration file, it is best not to edit an existing file, but to generate an entirely new `/etc/mail/sendmail.cf` file.

**WARNING**

Before replacing or making any changes to the `sendmail.cf` file, create a backup copy.

To add the desired functionality to Sendmail, edit the `/etc/mail/sendmail.mc` file as `root`. Once you are finished, restart the `sendmail` service and, if the `m4` package is installed, the `m4` macro processor will automatically generate a new `sendmail.cf` configuration file:

```
~$ systemctl restart sendmail
```
The default sendmail.cf file does not allow Sendmail to accept network connections from any host other than the local computer. To configure Sendmail as a server for other clients, edit the /etc/mail/sendmail.mc file, and either change the address specified in the Addr= option of the DAEMON_OPTIONS directive from 127.0.0.1 to the IP address of an active network device or comment out the DAEMON_OPTIONS directive all together by placing dnl at the beginning of the line. When finished, regenerate /etc/mail/sendmail.cf by restarting the service:

```shell
$]# systemctl restart sendmail
```

The default configuration in Red Hat Enterprise Linux works for most SMTP-only sites. However, it does not work for UUCP (UNIX-to-UNIX Copy Protocol) sites. If using UUCP mail transfers, the /etc/mail/sendmail.mc file must be reconfigured and a new /etc/mail/sendmail.cf file must be generated.

Consult the /usr/share/sendmail-cf/README file before editing any files in the directories under the /usr/share/sendmail-cf/ directory, as they can affect the future configuration of the /etc/mail/sendmail.cf file.

### 14.3.2.4. Masquerading

One common Sendmail configuration is to have a single machine act as a mail gateway for all machines on the network. For example, a company may want to have a machine called mail.example.com that handles all of their email and assigns a consistent return address to all outgoing mail.

In this situation, the Sendmail server must masquerade the machine names on the company network so that their return address is user@example.com instead of user@host.example.com.

To do this, add the following lines to /etc/mail/sendmail.mc:

```plaintext
FEATURE(always_add_domain)dnl
FEATURE(`masquerade_entire_domain')dnl
FEATURE(`masquerade_envelope')dnl
FEATURE(`allmasquerade')dnl
MASQUERADE_AS(`example.com.')dnl
MASQUERADE_DOMAIN(`example.com.')dnl
MASQUERADE_AS(example.com)dnl
```

After generating a new sendmail.cf file using the m4 macro processor, this configuration makes all mail from inside the network appear as if it were sent from example.com.

Note that administrators of mail servers, DNS and DHCP servers, as well as any provisioning applications, should agree on the host name format used in an organization. See the Red Hat Enterprise Linux 7 Networking Guide for more information on recommended naming practices.

### 14.3.2.5. Stopping Spam

Email spam can be defined as unnecessary and unwanted email received by a user who never requested the communication. It is a disruptive, costly, and widespread abuse of Internet communication standards.
Sendmail makes it relatively easy to block new spamming techniques being employed to send junk email. It even blocks many of the more usual spamming methods by default. Main anti-spam features available in sendmail are header checks, relaying denial (default from version 8.9), access database and sender information checks.

For example, forwarding of SMTP messages, also called relaying, has been disabled by default since Sendmail version 8.9. Before this change occurred, Sendmail directed the mail host (x.edu) to accept messages from one party (y.com) and sent them to a different party (z.net). Now, however, Sendmail must be configured to permit any domain to relay mail through the server. To configure relay domains, edit the /etc/mail/relay-domains file and restart Sendmail

```
~# systemctl restart sendmail
```

However users can also be sent spam from from servers on the Internet. In these instances, Sendmail's access control features available through the /etc/mail/access file can be used to prevent connections from unwanted hosts. The following example illustrates how this file can be used to both block and specifically allow access to the Sendmail server:

```
badspammer.com ERROR:550 "Go away and do not spam us anymore"
tux.badspammer.com OK 10.0 RELAY
```

This example shows that any email sent from badspammer.com is blocked with a 550 RFC-821 compliant error code, with a message sent back. Email sent from the tux.badspammer.com sub-domain, is accepted. The last line shows that any email sent from the 10.0.*.* network can be relayed through the mail server.

Because the /etc/mail/access.db file is a database, use the makemap command to update any changes. Do this using the following command as root:

```
~# makemap hash /etc/mail/access < /etc/mail/access
```

Message header analysis allows you to reject mail based on header contents. SMTP servers store information about an email's journey in the message header. As the message travels from one MTA to another, each puts in a Received header above all the other Received headers. It is important to note that this information may be altered by spammers.

The above examples only represent a small part of what Sendmail can do in terms of allowing or blocking access. See the /usr/share/sendmail-cf/README file for more information and examples.

Since Sendmail calls the Procmail MDA when delivering mail, it is also possible to use a spam filtering program, such as SpamAssassin, to identify and file spam for users. See Section 14.4.2.6, “Spam Filters” for more information about using SpamAssassin.

14.3.2.6. Using Sendmail with LDAP

Using LDAP is a very quick and powerful way to find specific information about a particular user from a much larger group. For example, an LDAP server can be used to look up a particular email address from a common corporate directory by the user's last name. In this kind of implementation, LDAP is largely separate from Sendmail, with LDAP storing the hierarchical user information and Sendmail only being given the result of LDAP queries in pre-addressed email messages.

However, Sendmail supports a much greater integration with LDAP, where it uses LDAP to replace separately maintained files, such as /etc/aliases and /etc/mail/virtusertables, on different
mail servers that work together to support a medium- to enterprise-level organization. In short, LDAP abstracts the mail routing level from Sendmail and its separate configuration files to a powerful LDAP cluster that can be leveraged by many different applications.

The current version of Sendmail contains support for LDAP. To extend the Sendmail server using LDAP, first get an LDAP server, such as OpenLDAP, running and properly configured. Then edit the /etc/mail/sendmail.mc to include the following:

```
LDAPROUTE_DOMAIN('yourdomain.com')dnl
FEATURE('ldap_routing')dnl
```

**NOTE**

This is only for a very basic configuration of Sendmail with LDAP. The configuration can differ greatly from this depending on the implementation of LDAP, especially when configuring several Sendmail machines to use a common LDAP server.

Consult /usr/share/sendmail-cf/README for detailed LDAP routing configuration instructions and examples.

Next, recreate the /etc/mail/sendmail.cf file by running the m4 macro processor and again restarting Sendmail. See Section 14.3.2.3, “Common Sendmail Configuration Changes” for instructions.

For more information on LDAP, see OpenLDAP in the System-Level Authentication Guide.

14.3.3. Fetchmail

Fetchmail is an MTA which retrieves email from remote servers and delivers it to the local MTA. Many users appreciate the ability to separate the process of downloading their messages located on a remote server from the process of reading and organizing their email in an MUA. Designed with the needs of dial-up users in mind, Fetchmail connects and quickly downloads all of the email messages to the mail spool file using any number of protocols, including POP3 and IMAP. It can even forward email messages to an SMTP server, if necessary.

**NOTE**

In order to use Fetchmail, first ensure the fetchmail package is installed on your system by running, as root:

```
~# yum install fetchmail
```

For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

Fetchmail is configured for each user through the use of a .fetchmailrc file in the user's home directory. If it does not already exist, create the .fetchmailrc file in your home directory.

Using preferences in the .fetchmailrc file, Fetchmail checks for email on a remote server and downloads it. It then delivers it to port 25 on the local machine, using the local MTA to place the email in the correct user's spool file. If Procmail is available, it is launched to filter the email and place it in a mailbox so that it can be read by an MUA.
14.3.3.1. Fetchmail Configuration Options

Although it is possible to pass all necessary options on the command line to check for email on a remote server when executing Fetchmail, using a `.fetchmailrc` file is much easier. Place any desired configuration options in the `.fetchmailrc` file for those options to be used each time the `fetchmail` command is issued. It is possible to override these at the time Fetchmail is run by specifying that option on the command line.

A user's `.fetchmailrc` file contains three classes of configuration options:

- **global options** — Gives Fetchmail instructions that control the operation of the program or provide settings for every connection that checks for email.

- **server options** — Specifies necessary information about the server being polled, such as the host name, as well as preferences for specific email servers, such as the port to check or number of seconds to wait before timing out. These options affect every user using that server.

- **user options** — Contains information, such as user name and password, necessary to authenticate and check for email using a specified email server.

Global options appear at the top of the `.fetchmailrc` file, followed by one or more server options, each of which designate a different email server that Fetchmail should check. User options follow server options for each user account checking that email server. Like server options, multiple user options may be specified for use with a particular server as well as to check multiple email accounts on the same server.

Server options are called into service in the `.fetchmailrc` file by the use of a special option verb, `poll` or `skip`, that precedes any of the server information. The `poll` action tells Fetchmail to use this server option when it is run, which checks for email using the specified user options. Any server options after a `skip` action, however, are not checked unless this server's host name is specified when Fetchmail is invoked. The `skip` option is useful when testing configurations in the `.fetchmailrc` file because it only checks skipped servers when specifically invoked, and does not affect any currently working configurations.

The following is an example of a `.fetchmailrc` file:

```
set postmaster "user1"
set bouncemail

poll pop.domain.com proto pop3
    user 'user1' there with password 'secret' is user1 here

poll mail.domain2.com
    user 'user5' there with password 'secret2' is user1 here
    user 'user7' there with password 'secret3' is user1 here
```

In this example, the global options specify that the user is sent email as a last resort (postmaster option) and all email errors are sent to the postmaster instead of the sender (bouncemail option). The set action tells Fetchmail that this line contains a global option. Then, two email servers are specified, one set to check using POP3, the other for trying various protocols to find one that works. Two users are checked using the second server option, but all email found for any user is sent to user1's mail spool. This allows multiple mailboxes to be checked on multiple servers, while appearing in a single MUA inbox. Each user's specific information begins with the user action.
Users are not required to place their password in the `.fetchmailrc` file. Omitting the `with password 'password'` section causes Fetchmail to ask for a password when it is launched.

Fetchmail has numerous global, server, and local options. Many of these options are rarely used or only apply to very specific situations. The `fetchmail` man page explains each option in detail, but the most common ones are listed in the following three sections.

### 14.3.3.2. Global Options

Each global option should be placed on a single line after a `set` action.

- `daemon seconds` — Specifies daemon-mode, where Fetchmail stays in the background. Replace `seconds` with the number of seconds Fetchmail is to wait before polling the server.
- `postmaster` — Specifies a local user to send mail to in case of delivery problems.
- `syslog` — Specifies the log file for errors and status messages. By default, this is `/var/log/maillog`.

### 14.3.3.3. Server Options

Server options must be placed on their own line in `.fetchmailrc` after a `poll` or `skip` action.

- `auth auth-type` — Replace `auth-type` with the type of authentication to be used. By default, password authentication is used, but some protocols support other types of authentication, including `kerberos_v5`, `kerberos_v4`, and `ssh`. If the any authentication type is used, Fetchmail first tries methods that do not require a password, then methods that mask the password, and finally attempts to send the password unencrypted to authenticate to the server.
- `interval number` — Polls the specified server every `number` of times that it checks for email on all configured servers. This option is generally used for email servers where the user rarely receives messages.
- `port port-number` — Replace `port-number` with the port number. This value overrides the default port number for the specified protocol.
- `proto protocol` — Replace `protocol` with the protocol, such as `pop3` or `imap`, to use when checking for messages on the server.
- `timeout seconds` — Replace `seconds` with the number of seconds of server inactivity after which Fetchmail gives up on a connection attempt. If this value is not set, a default of 300 seconds is used.

### 14.3.3.4. User Options

User options may be placed on their own line beneath a server option or on the same line as the server option. In either case, the defined options must follow the `user` option (defined below).

- `fetchall` — Orders Fetchmail to download all messages in the queue, including messages that have already been viewed. By default, Fetchmail only pulls down new messages.
- **fetchlimit** *number* — Replace *number* with the number of messages to be retrieved before stopping.

- **flush** — Deletes all previously viewed messages in the queue before retrieving new messages.

- **limit** *max-number-bytes* — Replace *max-number-bytes* with the maximum size in bytes that messages are allowed to be when retrieved by Fetchmail. This option is useful with slow network links, when a large message takes too long to download.

- **password** `'password'` — Replace *password* with the user's password.

- **preconnect** "*command*" — Replace *command* with a command to be executed before retrieving messages for the user.

- **postconnect** "*command*" — Replace *command* with a command to be executed after retrieving messages for the user.

- **ssl** — Activates SSL encryption. At the time of writing, the default action is to use the best available from SSL2, SSL3, SSLv3, TLS1, TLS1.1 and TLS1.2. Note that SSL2 is considered obsolete and due to the POODLE: SSLv3 vulnerability (CVE-2014-3566), SSLv3 should not be used. However, there is no way to force the use of TLS1 or newer, therefore ensure the mail server being connected to is configured not to use SSLv2 and SSLv3. Use stunnel where the server cannot be configured not to use SSLv2 and SSLv3.

- **sslproto** — Defines allowed SSL or TLS protocols. Possible values are SSL2, SSL3, SSLv23, and TLS1. The default value, if **sslproto** is omitted, unset, or set to an invalid value, is SSLv23. The default action is to use the best from SSLv2, SSLv3, TLSv1, TLS1.1 and TLS1.2. Note that setting any other value for SSL or TLS will disable all the other protocols. Due to the POODLE: SSLv3 vulnerability (CVE-2014-3566), it is recommended to omit this option, or set it to SSLv23, and configure the corresponding mail server not to use SSLv2 and SSLv3. Use stunnel where the server cannot be configured not to use SSLv2 and SSLv3.

- **user** "*username*" — Replace *username* with the user name used by Fetchmail to retrieve messages. This option must precede all other user options.

### 14.3.3.5. Fetchmail Command Options

Most Fetchmail options used on the command line when executing the *fetchmail* command mirror the .fetchmailrc configuration options. In this way, Fetchmail may be used with or without a configuration file. These options are not used on the command line by most users because it is easier to leave them in the .fetchmailrc file.

There may be times when it is desirable to run the *fetchmail* command with other options for a particular purpose. It is possible to issue command options to temporarily override a .fetchmailrc setting that is causing an error, as any options specified at the command line override configuration file options.

### 14.3.3.6. Informational or Debugging Options

Certain options used after the *fetchmail* command can supply important information.

- **--configdump** — Displays every possible option based on information from .fetchmailrc and Fetchmail defaults. No email is retrieved for any users when using this option.
-s — Executes Fetchmail in silent mode, preventing any messages, other than errors, from appearing after the fetchmail command.

-v — Executes Fetchmail in verbose mode, displaying every communication between Fetchmail and remote email servers.

-V — Displays detailed version information, lists its global options, and shows settings to be used with each user, including the email protocol and authentication method. No email is retrieved for any users when using this option.

14.3.3.7. Special Options

These options are occasionally useful for overriding defaults often found in the .fetchmailrc file.

- -a — Fetchmail downloads all messages from the remote email server, whether new or previously viewed. By default, Fetchmail only downloads new messages.

- -k — Fetchmail leaves the messages on the remote email server after downloading them. This option overrides the default behavior of deleting messages after downloading them.

- -l max-number-bytes — Fetchmail does not download any messages over a particular size and leaves them on the remote email server.

- --quit — Quits the Fetchmail daemon process.

More commands and .fetchmailrc options can be found in the fetchmail man page.

14.3.4. Mail Transport Agent (MTA) Configuration

A Mail Transport Agent (MTA) is essential for sending email. A Mail User Agent (MUA) such as Evolution or Mutt, is used to read and compose email. When a user sends an email from an MUA, the message is handed off to the MTA, which sends the message through a series of MTAs until it reaches its destination.

Even if a user does not plan to send email from the system, some automated tasks or system programs might use the mail command to send email containing log messages to the root user of the local system.

Red Hat Enterprise Linux 7 provides two MTAs: Postfix and Sendmail. If both are installed, Postfix is the default MTA. Note that Sendmail is considered deprecated in Red Hat Enterprise Linux 7.

14.4. MAIL DELIVERY AGENTS

Red Hat Enterprise Linux includes two primary MDAs, Procmail and mail. Both of the applications are considered LDAs and both move email from the MTA's spool file into the user's mailbox. However, Procmail provides a robust filtering system.

This section details only Procmail. For information on the mail command, consult its man page (man mail).

Procmail delivers and filters email as it is placed in the mail spool file of the localhost. It is powerful, gentle on system resources, and widely used. Procmail can play a critical role in delivering email to be read by email client applications.

Procmail can be invoked in several different ways. Whenever an MTA places an email into the mail
spool file, Procmail is launched. Procmail then filters and files the email for the MUA and quits. Alternatively, the MUA can be configured to execute Procmail any time a message is received so that messages are moved into their correct mailboxes. By default, the presence of /etc/procmailrc or of a ~/.procmailrc file (also called an rc file) in the user's home directory invokes Procmail whenever an MTA receives a new message.

By default, no system-wide rc files exist in the /etc directory and no .procmailrc files exist in any user's home directory. Therefore, to use Procmail, each user must construct a .procmailrc file with specific environment variables and rules.

Whether Procmail acts upon an email message depends upon whether the message matches a specified set of conditions or recipes in the rc file. If a message matches a recipe, then the email is placed in a specified file, is deleted, or is otherwise processed.

When Procmail starts, it reads the email message and separates the body from the header information. Next, Procmail looks for a /etc/procmailrc file and rc files in the /etc/procmailrcs/ directory for default, system-wide, Procmail environmental variables and recipes. Procmail then searches for a .procmailrc file in the user's home directory. Many users also create additional rc files for Procmail that are referred to within the .procmailrc file in their home directory.

14.4.1. Procmail Configuration

The Procmail configuration file contains important environmental variables. These variables specify things such as which messages to sort and what to do with the messages that do not match any recipes.

These environmental variables usually appear at the beginning of the ~/.procmailrc file in the following format:

```
env-variable="value"
```

In this example, `env-variable` is the name of the variable and `value` defines the variable.

There are many environment variables not used by most Procmail users and many of the more important environment variables are already defined by a default value. Most of the time, the following variables are used:

- **DEFAULT** — Sets the default mailbox where messages that do not match any recipes are placed.

  The default DEFAULT value is the same as $ORGMAIL.

- **INCLUDERC** — Specifies additional rc files containing more recipes for messages to be checked against. This breaks up the Procmail recipe lists into individual files that fulfill different roles, such as blocking spam and managing email lists, that can then be turned off or on by using comment characters in the user's ~/.procmailrc file.

  For example, lines in a user's ~/.procmailrc file may look like this:

  ```
  MAILDIR=$HOME/Msgs
  INCLUDERC=$MAILDIR/lists.rc
  INCLUDERC=$MAILDIR/spam.rc
  ```

  To turn off Procmail filtering of email lists but leaving spam control in place, comment out the first INCLUDERC line with a hash sign (#). Note that it uses paths relative to the current
directory.

- **LOCKSLEEP** — Sets the amount of time, in seconds, between attempts by Procmail to use a particular lockfile. The default is 8 seconds.

- **LOCKTIMEOUT** — Sets the amount of time, in seconds, that must pass after a lockfile was last modified before Procmail assumes that the lockfile is old and can be deleted. The default is 1024 seconds.

- **LOGFILE** — The file to which any Procmail information or error messages are written.

- **MAILDIR** — Sets the current working directory for Procmail. If set, all other Procmail paths are relative to this directory.

- **ORGMAIL** — Specifies the original mailbox, or another place to put the messages if they cannot be placed in the default or recipe-required location.

  By default, a value of `/var/spool/mail/$LOGNAME` is used.

- **SUSPEND** — Sets the amount of time, in seconds, that Procmail pauses if a necessary resource, such as swap space, is not available.

- **SWITCHRC** — Allows a user to specify an external file containing additional Procmail recipes, much like the INCLUDERC option, except that recipe checking is actually stopped on the referring configuration file and only the recipes on the SWITCHRC-specified file are used.

- **VERBOSE** — Causes Procmail to log more information. This option is useful for debugging.

Other important environmental variables are pulled from the shell, such as `LOGNAME`, the login name; `HOME`, the location of the home directory; and `SHELL`, the default shell.

A comprehensive explanation of all environments variables, and their default values, is available in the `procmailrc` man page.

### 14.4.2. Procmail Recipes

New users often find the construction of recipes the most difficult part of learning to use Procmail. This difficulty is often attributed to recipes matching messages by using regular expressions which are used to specify qualifications for string matching. However, regular expressions are not very difficult to construct and even less difficult to understand when read. Additionally, the consistency of the way Procmail recipes are written, regardless of regular expressions, makes it easy to learn by example. To see example Procmail recipes, see Section 14.4.2.5, “Recipe Examples”.

Procmail recipes take the following form:

```
:0 [flags] [: lockfile-name ]
* [ condition_1_special-condition-character condition_1_regular_expression ]
* [ condition_2_special-condition-character condition_2_regular_expression ]
* [ condition_N_special-condition-character condition_N_regular_expression ]
    special-action-character
    action-to-perform
```
The first two characters in a Procmail recipe are a colon and a zero. Various flags can be placed after
the zero to control how Procmail processes the recipe. A colon after the flags section specifies that a
lockfile is created for this message. If a lockfile is created, the name can be specified by replacing
\texttt{lockfile-name}.

A recipe can contain several conditions to match against the message. If it has no conditions, every
message matches the recipe. Regular expressions are placed in some conditions to facilitate message
matching. If multiple conditions are used, they must all match for the action to be performed.
Conditions are checked based on the flags set in the recipe's first line. Optional special characters
placed after the asterisk character (*) can further control the condition.

The \texttt{action-to-perform} argument specifies the action taken when the message matches one of the
conditions. There can only be one action per recipe. In many cases, the name of a mailbox is used here
to direct matching messages into that file, effectively sorting the email. Special action characters may
also be used before the action is specified. See Section 14.4.2.4, “Special Conditions and Actions” for
more information.

14.4.2.1. Delivering vs. Non-Delivering Recipes

The action used if the recipe matches a particular message determines whether it is considered a
delivering or non-delivering recipe. A delivering recipe contains an action that writes the message to a
file, sends the message to another program, or forwards the message to another email address. A non-
delivering recipe covers any other actions, such as a \texttt{nesting block}. A nesting block is a set of actions,
contained in braces \{ \}, that are performed on messages which match the recipe's conditions. Nesting
blocks can be nested inside one another, providing greater control for identifying and performing
actions on messages.

When messages match a delivering recipe, Procmail performs the specified action and stops
comparing the message against any other recipes. Messages that match non-delivering recipes
continue to be compared against other recipes.

14.4.2.2. Flags

Flags are essential to determine how or if a recipe's conditions are compared to a message. The \texttt{egrep}
utility is used internally for matching of the conditions. The following flags are commonly used:

- \texttt{A} – Specifies that this recipe is only used if the previous recipe without an \texttt{A} or \texttt{a} flag also
  matched this message.

- \texttt{a} – Specifies that this recipe is only used if the previous recipe with an \texttt{A} or \texttt{a} flag also
  matched this message \emph{and} was successfully completed.

- \texttt{B} – Parses the body of the message and looks for matching conditions.

- \texttt{b} – Uses the body in any resulting action, such as writing the message to a file or forwarding it.
  This is the default behavior.

- \texttt{c} – Generates a carbon copy of the email. This is useful with delivering recipes, since the
  required action can be performed on the message and a copy of the message can continue
  being processed in the \texttt{rc} files.

- \texttt{D} – Makes the \texttt{egrep} comparison case-sensitive. By default, the comparison process is not
  case-sensitive.
• E – While similar to the A flag, the conditions in the recipe are only compared to the message if the immediately preceding recipe without an E flag did not match. This is comparable to an else action.

• e – The recipe is compared to the message only if the action specified in the immediately preceding recipe fails.

• f – Uses the pipe as a filter.

• H – Parses the header of the message and looks for matching conditions. This is the default behavior.

• h – Uses the header in a resulting action. This is the default behavior.

• w – Tells Procmail to wait for the specified filter or program to finish, and reports whether or not it was successful before considering the message filtered.

• W – Is identical to w except that “Program failure” messages are suppressed.

For a detailed list of additional flags, see the procmailrc man page.

14.4.2.3. Specifying a Local Lockfile

Lockfiles are very useful with Procmail to ensure that more than one process does not try to alter a message simultaneously. Specify a local lockfile by placing a colon (:) after any flags on a recipe's first line. This creates a local lockfile based on the destination file name plus whatever has been set in the LOCKEXT global environment variable.

Alternatively, specify the name of the local lockfile to be used with this recipe after the colon.

14.4.2.4. Special Conditions and Actions

Special characters used before Procmail recipe conditions and actions change the way they are interpreted.

The following characters may be used after the asterisk character (*) at the beginning of a recipe's condition line:

• ! – In the condition line, this character inverts the condition, causing a match to occur only if the condition does not match the message.

• < – Checks if the message is under a specified number of bytes.

• > – Checks if the message is over a specified number of bytes.

The following characters are used to perform special actions:

• ! – In the action line, this character tells Procmail to forward the message to the specified email addresses.

• $ – Refers to a variable set earlier in the rc file. This is often used to set a common mailbox that is referred to by various recipes.

• | – Starts a specified program to process the message.

• { and } – Constructs a nesting block, used to contain additional recipes to apply to matching
messages.

If no special character is used at the beginning of the action line, Procmail assumes that the action line is specifying the mailbox in which to write the message.

14.4.2.5. Recipe Examples

Procmail is an extremely flexible program, but as a result of this flexibility, composing Procmail recipes from scratch can be difficult for new users.

The best way to develop the skills to build Procmail recipe conditions stems from a strong understanding of regular expressions combined with looking at many examples built by others. A thorough explanation of regular expressions is beyond the scope of this section. The structure of Procmail recipes and useful sample Procmail recipes can be found at various places on the Internet. The proper use and adaptation of regular expressions can be derived by viewing these recipe examples. In addition, introductory information about basic regular expression rules can be found in the grep(1) man page.

The following simple examples demonstrate the basic structure of Procmail recipes and can provide the foundation for more intricate constructions.

A basic recipe may not even contain conditions, as is illustrated in the following example:

```
:0:
 new-mail.spool
```

The first line specifies that a local lockfile is to be created but does not specify a name, so Procmail uses the destination file name and appends the value specified in the LOCKEXT environment variable. No condition is specified, so every message matches this recipe and is placed in the single spool file called new-mail.spool, located within the directory specified by the MAILDIR environment variable. An MUA can then view messages in this file.

A basic recipe, such as this, can be placed at the end of all rc files to direct messages to a default location.

The following example matched messages from a specific email address and throws them away.

```
:0
 * ^From: spammer@domain.com
 /dev/null
```

With this example, any messages sent by spammer@domain.com are sent to the /dev/null device, deleting them.
WARNING

Be certain that rules are working as intended before sending messages to /dev/null for permanent deletion. If a recipe inadvertently catches unintended messages, and those messages disappear, it becomes difficult to troubleshoot the rule.

A better solution is to point the recipe's action to a special mailbox, which can be checked from time to time to look for false positives. Once satisfied that no messages are accidentally being matched, delete the mailbox and direct the action to send the messages to /dev/null.

The following recipe grabs email sent from a particular mailing list and places it in a specified folder.

```plaintext
:0:
* ^((From|Cc|To).*tux-lug
  tuxlug
```

Any messages sent from the tux-lug@domain.com mailing list are placed in the tuxlug mailbox automatically for the MUA. Note that the condition in this example matches the message if it has the mailing list's email address on the From, Cc, or To lines.

Consult the many Procmail online resources available in Section 14.6, “Additional Resources” for more detailed and powerful recipes.

14.4.2.6. Spam Filters

Because it is called by Sendmail, Postfix, and Fetchmail upon receiving new emails, Procmail can be used as a powerful tool for combating spam.

This is particularly true when Procmail is used in conjunction with SpamAssassin. When used together, these two applications can quickly identify spam emails, and sort or destroy them.

SpamAssassin uses header analysis, text analysis, blacklists, a spam-tracking database, and self-learning Bayesian spam analysis to quickly and accurately identify and tag spam.

**NOTE**

In order to use SpamAssassin, first ensure the spamassassin package is installed on your system by running, as root:

```
~]$# yum install spamassassin
```

For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

The easiest way for a local user to use SpamAssassin is to place the following line near the top of the ~/.procmailrc file:
The /etc/mail/spamassassin/spamassassin-default.rc contains a simple Procmail rule that activates SpamAssassin for all incoming email. If an email is determined to be spam, it is tagged in the header as such and the title is prepended with the following pattern:

```
*****SPAM*****
```

The message body of the email is also prepended with a running tally of what elements caused it to be diagnosed as spam.

To file email tagged as spam, a rule similar to the following can be used:

```
:0 Hw * ^X-Spam-Status: Yes spam
```

This rule files all email tagged in the header as spam into a mailbox called spam.

Since SpamAssassin is a Perl script, it may be necessary on busy servers to use the binary SpamAssassin daemon (spamd) and the client application (spamc). Configuring SpamAssassin this way, however, requires root access to the host.

To start the spamd daemon, type the following command:

```
~# systemctl start spamassassin
```

To start the SpamAssassin daemon when the system is booted, run:

```
systemctl enable spamassassin.service
```

See Chapter 9, Managing Services with systemd for more information about starting and stopping services.

To configure Procmail to use the SpamAssassin client application instead of the Perl script, place the following line near the top of the ~/.procmailrc file. For a system-wide configuration, place it in /etc/procmailrc:

```
INCLUDERC=/etc/mail/spamassassin/spamassassin-spamc.rc
```

14.5. MAIL USER AGENTS

Red Hat Enterprise Linux offers a variety of email programs, both, graphical email client programs, such as Evolution, and text-based email programs such as mutt.

The remainder of this section focuses on securing communication between a client and a server.

14.5.1. Securing Communication

Popular MUAs included with Red Hat Enterprise Linux, such as Evolution and Mutt offer SSL-encrypted email sessions.

Like any other service that flows over a network unencrypted, important email information, such as user names, passwords, and entire messages, may be intercepted and viewed by users on the network. Additionally, since the standard POP and IMAP protocols pass authentication information unencrypted,
it is possible for an attacker to gain access to user accounts by collecting user names and passwords as they are passed over the network.

14.5.1.1. Secure Email Clients

Most Linux MUAs designed to check email on remote servers support SSL encryption. To use SSL when retrieving email, it must be enabled on both the email client and the server.

SSL is easy to enable on the client-side, often done with the click of a button in the MUA’s configuration window or via an option in the MUA’s configuration file. Secure IMAP and POP have known port numbers (993 and 995, respectively) that the MUA uses to authenticate and download messages.

14.5.1.2. Securing Email Client Communications

Offering SSL encryption to IMAP and POP users on the email server is a simple matter.

First, create an SSL certificate. This can be done in two ways: by applying to a Certificate Authority (CA) for an SSL certificate or by creating a self-signed certificate.

**WARNING**

Self-signed certificates should be used for testing purposes only. Any server used in a production environment should use an SSL certificate signed by a CA.

To create a self-signed SSL certificate for IMAP or POP, change to the /etc/pki/dovecot/ directory, edit the certificate parameters in the /etc/pki/dovecot/dovecot-openssl.cnf configuration file as you prefer, and type the following commands, as root:

```bash

dovecot]# rm -f certs/dovecot.pem private/dovecot.pem
dovecot]# /usr/libexec/dovecot/mkcert.sh
```

Once finished, make sure you have the following configurations in your /etc/dovecot/conf.d/10-ssl.conf file:

```conf
ssl_cert = </etc/pki/dovecot/certs/dovecot.pem
ssl_key = </etc/pki/dovecot/private/dovecot.pem
```

Issue the following command to restart the dovecot daemon:

```bash
~]# systemctl restart dovecot
```

Alternatively, the **stunnel** command can be used as an encryption wrapper around the standard, non-secure connections to IMAP or POP services.

The stunnel utility uses external OpenSSL libraries included with Red Hat Enterprise Linux to provide strong cryptography and to protect the network connections. It is recommended to apply to a CA to obtain an SSL certificate, but it is also possible to create a self-signed certificate.
See *Using stunnel* in the Red Hat Enterprise Linux 7 Security Guide for instructions on how to install *stunnel* and create its basic configuration. To configure *stunnel* as a wrapper for *IMAPS* and *POP3S*, add the following lines to the `/etc/stunnel/stunnel.conf` configuration file:

```
[pop3s]
accept = 995
connect = 110

[imaps]
accept = 993
connect = 143
```

The Security Guide also explains how to start and stop *stunnel*. Once you start it, it is possible to use an *IMAP* or a *POP* email client and connect to the email server using SSL encryption.

### 14.6. ADDITIONAL RESOURCES

The following is a list of additional documentation about email applications.

#### 14.6.1. Installed Documentation

- Information on configuring Sendmail is included with the *sendmail* and *sendmail-cf* packages.
  - `/usr/share/sendmail-cf/README` — Contains information on the *m4* macro processor, file locations for Sendmail, supported mailers, how to access enhanced features, and more.

  In addition, the *sendmail* and *aliases* man pages contain helpful information covering various Sendmail options and the proper configuration of the Sendmail `/etc/mail/aliases` file.

- `/usr/share/doc/postfix-version-number/` — Contains a large amount of information on how to configure Postfix. Replace `version-number` with the version number of Postfix.

- `/usr/share/doc/fetchmail-version-number/` — Contains a full list of Fetchmail features in the `FEATURES` file and an introductory FAQ document. Replace `version-number` with the version number of Fetchmail.

- `/usr/share/doc/procmail-version-number/` — Contains a README file that provides an overview of Procmail, a FEATURES file that explores every program feature, and an FAQ file with answers to many common configuration questions. Replace `version-number` with the version number of Procmail.

  When learning how Procmail works and creating new recipes, the following Procmail man pages are invaluable:

    - `procmail` — Provides an overview of how Procmail works and the steps involved with filtering email.
    - `procmailrc` — Explains the `rc` file format used to construct recipes.
    - `procmailex` — Gives a number of useful, real-world examples of Procmail recipes.
    - `procmailsc` — Explains the weighted scoring technique used by Procmail to match a particular recipe to a message.
14.6.2. Online Documentation

- **How to configure postfix with TLS?** — A Red Hat Knowledgebase article that describes configuring postfix to use TLS.

- **How to configure a Sendmail Smart Host** — A Red Hat Knowledgebase solution that describes configuring a sendmail Smart Host.

- [http://www.sendmail.com/](http://www.sendmail.com/) — Contains news, interviews and articles concerning Sendmail, including an expanded view of the many options available.

- [http://www.postfix.org/](http://www.postfix.org/) — The Postfix project home page contains a wealth of information about Postfix. The mailing list is a particularly good place to look for information.

- [http://www.procmail.org/](http://www.procmail.org/) — The home page for Procmail with links to assorted mailing lists dedicated to Procmail as well as various FAQ documents.

14.6.3. Related Books

- **Sendmail Milters: A Guide for Fighting Spam** by Bryan Costales and Marcia Flynt; Addison-Wesley — A good Sendmail guide that can help you customize your mail filters.

- **Sendmail** by Bryan Costales with Eric Allman et al.; O'Reilly & Associates — A good Sendmail reference written with the assistance of the original creator of Delivermail and Sendmail.

- **Removing the Spam: Email Processing and Filtering** by Geoff Mulligan; Addison-Wesley Publishing Company — A volume that looks at various methods used by email administrators using established tools, such as Sendmail and Procmail, to manage spam problems.

- **Internet Email Protocols: A Developer's Guide** by Kevin Johnson; Addison-Wesley Publishing Company — Provides a very thorough review of major email protocols and the security they provide.

- **Managing IMAP** by Dianna Mullet and Kevin Mullet; O'Reilly & Associates — Details the steps required to configure an IMAP server.
CHAPTER 15. FILE AND PRINT SERVERS

This chapter guides you through the installation and configuration of Samba, an open source implementation of the Server Message Block (SMB) and common Internet file system (CIFS) protocol, and vsftpd, the primary FTP server shipped with Red Hat Enterprise Linux. Additionally, it explains how to use the Print Settings tool to configure printers.

15.1. SAMBA

Samba implements the Server Message Block (SMB) protocol in Red Hat Enterprise Linux. The SMB protocol is used to access resources on a server, such as file shares and shared printers. Additionally, Samba implements the Distributed Computing Environment Remote Procedure Call (DCE RPC) protocol used by Microsoft Windows.

You can run Samba as:

- An Active Directory (AD) or NT4 domain member
- A standalone server
- An NT4 Primary Domain Controller (PDC) or Backup Domain Controller (BDC)

Independently of the installation mode, you can optionally share directories and printers. This enables Samba to act as a file and print server.

NOTE

Red Hat does not support running Samba as an AD domain controller (DC).

15.1.1. The Samba Services

Samba provides the following services:

smbd

This service provides file sharing and printing services using the SMB protocol. Additionally, the service is responsible for resource locking and for authenticating connecting users. The `smbd systemctl` service starts and stops the `smbd` daemon.

To use the `smbd` service, install the `samba` package.

nmbd

This service provides host name and IP resolution using the NetBIOS over IP protocol. Additionally to the name resolution, the `nmbd` service enables browsing the SMB network to locate domains, work groups, hosts, file shares, and printers. For this, the service either reports this information directly to the broadcasting client or forwards it to a local or master browser. The `nmbd systemctl` service starts and stops the `nmbd` daemon.

Note that modern SMB networks use DNS to resolve clients and IP addresses.

To use the `nmbd` service, install the `samba` package.

winbind

The `winbind` service provides an interface for the Name Service Switch (NSS) to use AD or NT4...
domain users and groups on the local system. This enables, for example, domain users to authenticate to services hosted on a Samba server or to other local services. The winbind systemd service starts and stops the winbindd daemon.

To use the winbindd service, install the samba-winbind package.

15.1.2. Verifying the smb.conf File by Using the testparm Utility

The testparm utility verifies that the Samba configuration in the /etc/samba/smb.conf file is correct. The utility detects invalid parameters and values, but also incorrect settings, such as for ID mapping. If testparm reports no problem, the Samba services will successfully load the /etc/samba/smb.conf file. Note that testparm cannot verify that the configured services will be available or work as expected.

IMPORTANT

Red Hat recommends that you verify the /etc/samba/smb.conf file by using testparm after each modification of this file.

To verify the /etc/samba/smb.conf file, run the testparm utility as the root user. If testparm reports incorrect parameters, values, or other errors in the configuration, fix the problem and run the utility again.

Example 15.1. Using testparm

The following output reports a non-existent parameter and an incorrect ID mapping configuration:

~]# testparm
Load smb config files from /etc/samba/smb.conf
rlimit_max: increasing rlimit_max (1024) to minimum Windows limit (16384)
Unknown parameter encountered: "log levell"
Processing section "[example_share]"
Loaded services file OK.
ERROR: The idmap range for the domain * (tdb) overlaps with the range of DOMAIN (ad)!

Server role: ROLE_DOMAIN_MEMBER

Press enter to see a dump of your service definitions

# Global parameters
[global]
...

[example_share]
...

15.1.3. Understanding the Samba Security Modes
The `security` parameter in the `[global]` section in the `/etc/samba/smb.conf` file manages how Samba authenticates users that are connecting to the service. Depending on the mode you install Samba in, the parameter must be set to different values:

- **On an AD domain member, set `security = ad`.**
  
  In this mode, Samba uses Kerberos to authenticate AD users.
  
  For details about setting up Samba as a domain member, see Section 15.1.5, “Setting up Samba as a Domain Member”.

- **On a standalone server, set `security = user`.**
  
  In this mode, Samba uses a local database to authenticate connecting users.
  
  For details about setting up Samba as a standalone server, see Section 15.1.4, “Setting up Samba as a Standalone Server”.

- **On an NT4 PDC or BDC, set `security = user`.**
  
  In this mode, Samba authenticates users to a local or LDAP database.

- **On an NT4 domain member, set `security = domain`.**
  
  In this mode, Samba authenticates connecting users to an NT4 PDC or BDC. You cannot use this mode on AD domain members.
  
  For details about setting up Samba as a domain member, see Section 15.1.5, “Setting up Samba as a Domain Member”.

For further details, see the description of the `security` parameter in the `smb.conf(5)` man page.

**15.1.4. Setting up Samba as a Standalone Server**

In certain situations, administrators want to set up a Samba server that is not a member of a domain. In this installation mode, Samba authenticates users to a local database instead of to a central DC. Additionally, you can enable guest access to allow users to connect to one or multiple services without authentication.

**15.1.4.1. Setting up the Server Configuration for the Standalone Server**

To set up Samba as a standalone server:

**Procedure 15.1. Setting up Samba as a Standalone Server**

1. Install the `samba` package:

   ```
   ~]# yum install samba
   ```

2. Edit the `/etc/samba/smb.conf` file and set the following parameters:

   ```
   [global]
   workgroup = Example-WG
   netbios name = Server
   security = user
   ```
log file = /var/log/samba/%m.log
log level = 1

This configuration defines a standalone server named Server within the Example-WG work
group. Additionally, this configuration enables logging on a minimal level (1) and log files will
be stored in the /var/log/samba/ directory. Samba will expand the %m macro in the log
file parameter to the NetBIOS name of connecting clients. This enables individual log files for
each client.

For further details, see the parameter descriptions in the smb.conf(5) man page.

3. Configure file or printer sharing. See:
   - Section 15.1.7, “Configuring File Shares on a Samba Server”
   - Section 15.1.8, “Setting up a Samba Print Server”

4. Verify the /etc/samba/smb.conf file:
   ~# testparm
   For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

5. If you set up shares that require authentication, create the user accounts. For details, see
   Section 15.1.4.2, “Creating and Enabling Local User Accounts”.

6. Open the required ports and reload the firewall configuration by using the firewall-cmd utility:
   ~# firewall-cmd --permanent --add-port={139/tcp,445/tcp}
   ~# firewall-cmd --reload

7. Start the smb service:
   ~# systemctl start smb

8. Optionally, enable the smb service to start automatically when the system boots:
   ~# systemctl enable smb

15.1.4.2. Creating and Enabling Local User Accounts

To enable users to authenticate when they connect to a share, you must create the accounts on the
Samba host both in the operating system and in the Samba database. Samba requires the operating
system account to validate the Access Control Lists (ACL) on file system objects and the Samba
account to authenticate connecting users.

If you use the passdb backend = tdbsam default setting, Samba stores user accounts in the
/var/lib/samba/private/passdb.tdb database.

For example, to create the example Samba user:
Procedure 15.2. Creating a Samba User

1. Create the operating system account:

```bash
~]# useradd -M -s /sbin/nologin example
```

The previous command adds the example account without creating a home directory. If the account is only used to authenticate to Samba, assign the `/sbin/nologin` command as shell to prevent the account from logging in locally.

2. Set a password to the operating system account to enable it:

```bash
~]# passwd example
Enter new UNIX password: password
Retype new UNIX password: password
passwd: password updated successfully
```

Samba does not use the password set on the operating system account to authenticate. However, you need to set a password to enable the account. If an account is disabled, Samba denies access if this user connects.

3. Add the user to the Samba database and set a password to the account:

```bash
~]# smbpasswd -a example
New SMB password: password
Retype new SMB password: password
Added user example.
```

Use this password to authenticate when using this account to connect to a Samba share.

4. Enable the Samba account:

```bash
~]# smbpasswd -e example
Enabled user example.
```

15.1.5. Setting up Samba as a Domain Member

Administrators running an AD or NT4 domain often want to use Samba to join their Red Hat Enterprise Linux server as a member to the domain. This enables you to:

- Access domain resources on other domain members
- Authenticate domain users to local services, such as sshd
- Share directories and printers hosted on the server to act as a file and print server

15.1.5.1. Joining a Domain

To join a Red Hat Enterprise Linux system to a domain:

Procedure 15.3. Joining a Red Hat Enterprise Linux System to a Domain

1. Install the following packages:
~]# yum install realmd oddjob-mkhome oddjob samba-winbind-clients
   samba-winbind samba-common-tools

2. If you join an AD, additionally install the samba-winbind-krb5-locator package:
   ~]# yum install samba-winbind-krb5-locator

   This plug-in enables Kerberos to locate the Key Distribution Center (KDC) based on AD sites
   using DNS service records.

3. Optionally, rename the existing /etc/samba/smb.conf Samba configuration file:
   ~]# mv /etc/samba/smb.conf /etc/samba/smb.conf.old

4. Join the domain. For example, to join a domain named ad.example.com
   ~]# realm join --client-software=winbind ad.example.com

   Using the previous command, the realm utility automatically:
   - Creates a /etc/samba/smb.conf file for a membership in the ad.example.com domain
   - Adds the winbind module for user and group lookups to the /etc/nsswitch.conf file
   - Configures the Kerberos client in the /etc/krb5.conf file for the AD membership
   - Updates the Pluggable Authentication Module (PAM) configuration files in the
     /etc/pam.d/ directory
   - Starts the winbind service and enables the service to start when the system boots

   For further details about the realm utility, see the realm(8) man page and the corresponding
   section in the Red Hat Windows Integration Guide.

5. Optionally, set an alternative ID mapping back end or customized ID mapping settings in the
   /etc/samba/smb.conf file. For details, see Section 15.1.5.3, “Understanding ID Mapping”.

6. Optionally, verify the configuration. See Section 15.1.5.2, “Verifying That Samba Was Correctly
   Joined As a Domain Member”.

15.1.5.2. Verifying That Samba Was Correctly Joined As a Domain Member

After you joined a Red Hat Enterprise Linux as a domain member, you can run different tests to verify
that the join succeeded. See:

- the section called “Verifying That the Operating System Can Retrieve Domain User Accounts
  and Groups”
- the section called “Verifying If AD Domain Users Can Obtain a Kerberos Ticket”
- the section called “Listing the Available Domains”

Verifying That the Operating System Can Retrieve Domain User Accounts and Groups
Use the `getent` utility to verify that the operating system can retrieve domain users and groups. For example:

- To query the administrator account in the AD domain:
  ```bash
  ~]# getent passwd AD\administrator
  AD\administrator:*:10000:10000::/home/administrator@AD:/bin/bash
  ```

- To query the members of the Domain Users group in the AD domain:
  ```bash
  ~]# getent group "AD\Domain Users"
  AD\domain users:x:10000:user
  ```

If the command works correctly, verify that you can use domain users and groups when you set permissions on files and directories. For example, to set the owner of the `/srv/samba/example.txt` file to administrator and the group to Domain Admins:

```bash
~]# chown administrator:"Domain Admins" /srv/samba/example.txt
```

### Verifying If AD Domain Users Can Obtain a Kerberos Ticket

In an AD environment, users can obtain a Kerberos ticket from the DC. For example, to verify if the administrator user can obtain a Kerberos ticket:

**NOTE**

To use the `kinit` and `klist` utilities, install the `krb5-workstation` package on the Samba domain member.

**Procedure 15.4. Obtaining a Kerberos Ticket**

1. Obtain a ticket for the `administrator@AD.EXAMPLE.COM` principal:
   ```bash
   ~]# kinit administrator@AD.EXAMPLE.COM
   ```

2. Display the cached Kerberos ticket:
   ```bash
   ~]# klist
   Ticket cache: KEYRING:persistent:0:0
   Default principal: administrator@AD.EXAMPLE.COM
   Valid starting       Expires              Service principal
   krbtgt/AD.EXAMPLE.COM@AD.EXAMPLE.COM
   renew until 18.09.2017 14:46:19
   ```

### Listing the Available Domains

To list all domains available through the `winbindd` service, enter:

```bash
~]# wbinfo --all-domains
```

If Samba was successfully joined as a domain member, the command displays the built-in and local host name, as well as the domain Samba is a member of including trusted domains.
15.1.5.3. Understanding ID Mapping

Windows domains distinguish users and groups by unique Security Identifiers (SID). However, Linux requires unique UIDs and GIDs for each user and group. If you run Samba as a domain member, the `winbindd` service is responsible for providing information about domain users and groups to the operating system.

To enable the `winbindd` service to provide unique IDs for users and groups to Linux, you must configure ID mapping in the `/etc/samba/smb.conf` file for:

- The local database (default domain)
- The AD or NT4 domain the Samba server is a member of
- Each trusted domain from which users must be able to access resources on this Samba server

15.1.5.3.1. Planning ID Ranges

Regardless of whether you store the Linux UIDs and GIDs in AD or if you configure Samba to generate them, each domain configuration requires a unique ID range that must not overlap with any of the other domains.

**WARNING**

If you set overlapping ID ranges, Samba fails to work correctly.

Example 15.3. Unique ID Ranges

The following shows non-overlapping ID mapping ranges for the default (*), `AD-DOM`, and the `TRUST-DOM` domains.

```
[globals]
...
idmap config * : backend = tdb
idmap config * : range = 10000-999999

idmap config AD-DOM:backend = rid
idmap config AD-DOM:range = 2000000-2999999

idmap config TRUST-DOM:backend = rid
idmap config TRUST-DOM:range = 4000000-4999999
```
IMPORTANT

You can only assign one range per domain. Therefore, leave enough space between the domains ranges. This enables you to extend the range later if your domain grows.

If you later assign a different range to a domain, the ownership of files and directories previously created by these users and groups will be lost.

15.1.5.3.2. The * Default Domain

In a domain environment, you add one ID mapping configuration for each of the following:

- The domain the Samba server is a member of
- Each trusted domain that should be able to access the Samba server

However, for all other objects, Samba assigns IDs from the default domain. This includes:

- Local Samba users and groups
- Samba built-in accounts and groups, such as BUILTIN\Administrators

IMPORTANT

You must configure the default domain as described in this section to enable Samba to operate correctly.

The default domain back end must be writable to permanently store the assigned IDs.

For the default domain, you can use one of the following back ends:

tdb

When you configure the default domain to use the tdb back end, set an ID range that is big enough to include objects that will be created in the future and that are not part of a defined domain ID mapping configuration.

For example, set the following in the [global] section in the /etc/samba/smb.conf file:

```
idmap config * : backend = tdb
idmap config * : range = 10000-999999
```

For further details, see Section 15.1.5.4.1, “Using the tdb ID Mapping Back End”.

autorid

When you configure the default domain to use the autorid back end, adding additional ID mapping configurations for domains is optional.

For example, set the following in the [global] section in the /etc/samba/smb.conf file:
15.1.5.4. The Different ID Mapping Back Ends

Samba provides different ID mapping back ends for specific configurations. The most frequently used back ends are:

### Table 15.1. Frequently Used ID Mapping Back Ends

<table>
<thead>
<tr>
<th>Back End</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>
<tr>
<td>tdb</td>
<td>The * default domain only</td>
</tr>
<tr>
<td>ad</td>
<td>AD domains only</td>
</tr>
<tr>
<td>rid</td>
<td>AD and NT4 domains</td>
</tr>
<tr>
<td>autorid</td>
<td>AD, NT4, and the * default domain</td>
</tr>
</tbody>
</table>

The following sections describe the benefits, recommended scenarios where to use the back end, and how to configure it.

15.1.5.4.1. Using the tdb ID Mapping Back End

The winbindd service uses the writable tdb ID mapping back end by default to store Security Identifier (SID), UID, and GID mapping tables. This includes local users, groups, and built-in principals.

Use this back end only for the * default domain. For example:

```
idmap config * : backend = tdb
idmap config * : range = 10000-999999
```

For further details about the * default domain, see Section 15.1.5.3.2, “The * Default Domain”.

15.1.5.4.2. Using the ad ID Mapping Back End

The ad ID mapping back end implements a read-only API to read account and group information from AD. This provides the following benefits:

- All user and group settings are stored centrally in AD.
- User and group IDs are consistent on all Samba servers that use this back end.
- The IDs are not stored in a local database which can corrupt, and therefore file ownerships cannot be lost.

The ad back end reads the following attributes from AD:
### Table 15.2. Attributes the ad Back End Reads from User and Group Objects

<table>
<thead>
<tr>
<th>AD Attribute Name</th>
<th>Object Type</th>
<th>Mapped to</th>
</tr>
</thead>
<tbody>
<tr>
<td>sAMAccountName</td>
<td>User and group</td>
<td>User or group name, depending on the object</td>
</tr>
<tr>
<td>uidNumber</td>
<td>User</td>
<td>User ID (UID)</td>
</tr>
<tr>
<td>gidNumber</td>
<td>Group</td>
<td>Group ID (GID)</td>
</tr>
<tr>
<td>loginShell[^a]</td>
<td>User</td>
<td>Path to the shell of the user</td>
</tr>
<tr>
<td>unixHomeDirectory[^a]</td>
<td>User</td>
<td>Path to the home directory of the user</td>
</tr>
<tr>
<td>primaryGroupID[^b]</td>
<td>User</td>
<td>Primary group ID</td>
</tr>
</tbody>
</table>

[^a] Samba only reads this attribute if you set `idmap config DOMAIN:unix_nss_info = yes.`

[^b] Samba only reads this attribute if you set `idmap config DOMAIN:unix_primary_group = yes.`

### 15.1.5.4.2.1. Prerequisites of the ad Back End

To use the ad ID mapping back end:

- Both users and groups must have unique IDs set in AD, and the IDs must be within the range configured in the `/etc/samba/smb.conf` file. Objects whose IDs are outside of the range will not be available on the Samba server.

- Users and groups must have all required attributes set in AD. If required attributes are missing, the user or group will not be available on the Samba server. The required attributes depend on your configuration. See Table 15.2, “Attributes the ad Back End Reads from User and Group Objects”.

### 15.1.5.4.2.2. Configuring the ad Back End

To configure a Samba AD member to use the ad ID mapping back end:

Procedure 15.5. Configuring the ad Back End on a Domain Member

1. Edit the `[global]` section in the `/etc/samba/smb.conf` file:
   
   a. Add an ID mapping configuration for the default domain (`*`) if it does not exist. For example:

   ```
   idmap config * : backend = tdb
   idmap config * : range = 10000-999999
   ```

   For further details about the default domain configuration, see Section 15.1.5.3.2, “The * Default Domain”.

234
b. Enable the ad ID mapping back end for the AD domain:

```
  idmap config DOMAIN : backend = ad
```

c. Set the range of IDs that is assigned to users and groups in the AD domain. For example:

```
  idmap config DOMAIN : range = 2000000-2999999
```

**IMPORTANT**

The range must not overlap with any other domain configuration on this server. Additionally, the range must be set big enough to include all IDs assigned in the future. For further details, see Section 15.1.5.3.1, “Planning ID Ranges”.

d. Set that Samba uses the RFC 2307 schema when reading attributes from AD:

```
  idmap config DOMAIN : schema_mode = rfc2307
```

e. To enable Samba to read the login shell and the path to the users home directory from the corresponding AD attribute, set:

```
  idmap config DOMAIN : unix_nss_info = yes
```

Alternatively, you can set a uniform domain-wide home directory path and login shell that is applied to all users. For example:

```
  template shell = /bin/bash
  template homedir = /home/%U
```

For details about variable substitution, see the VARIABLE SUBSTITUTIONS section in the smb.conf(5) man page.

f. By default, Samba uses the primaryGroupID attribute of a user object as the user's primary group on Linux. Alternatively, you can configure Samba to use the value set in the gidNumber attribute instead:

```
  idmap config DOMAIN : unix_primary_group = yes
```

2. Verify the `/etc/samba/smb.conf` file:

```
~]$ testparm
```

For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

3. Reload the Samba configuration:

```
~]$ smbcontrol all reload-config
```

4. Verify that the settings work as expected. See the section called “Verifying That the Operating System Can Retrieve Domain User Accounts and Groups”.
For further details, see the smb.conf(5) and idmap_ad(8) man pages.

### 15.1.5.4.3. Using the `rid` ID Mapping Back End

Samba can use the relative identifier (RID) of a Windows SID to generate an ID on Red Hat Enterprise Linux.

**NOTE**

The RID is the last part of a SID. For example, if the SID of a user is S-1-5-21-5421822485-1151247151-421485315-30014, then 30014 is the corresponding RID. For details, how Samba calculates the local ID, see the idmap_rid(8) man page.

The `rid` ID mapping back end implements a read-only API to calculate account and group information based on an algorithmic mapping scheme for AD and NT4 domains. When you configure the back end, you must set the lowest and highest RID in the `idmap config DOMAIN : range` parameter. Samba will not map users or groups with a lower or higher RID than set in this parameter.

**IMPORTANT**

As a read-only back end, `rid` cannot assign new IDs, such as for BUILTIN groups. Therefore, do not use this back end for the * default domain.

### 15.1.5.4.3.1. Benefits and Drawbacks of Using the `rid` Back End

**Benefits**

- All domain users and groups that have an RID within the configured range are automatically available on the domain member.

- You do not need to manually assign IDs, home directories, and login shells.

**Drawbacks**

- All domain users get the same login shell and home directory assigned. However, you can use variables.

- User and group IDs are only the same across Samba domain members if all use the `rid` back end with the same ID range settings.

- You cannot exclude individual users or groups from being available on the domain member. Only users and groups outside of the configured range are excluded.

- Based on the formulas the `winbindd` service uses to calculate the IDs, duplicate IDs can occur in multi-domain environments if objects in different domains have the same RID.

### 15.1.5.4.3.2. Configuring the `rid` Back End

To configure a Samba domain member to use the `rid` ID mapping back end:

**Procedure 15.6. Configuring the `rid` Back End on a Domain Member**

1. Edit the `[global]` section in the `/etc/samba/smb.conf` file:
a. Add an ID mapping configuration for the default domain (*) if it does not exist. For example:

```
idmap config * : backend = tdb
idmap config * : range = 10000-999999
```

For further details about the default domain configuration, see Section 15.1.5.3.2, “The * Default Domain”.

b. Enable the rid ID mapping back end for the domain:

```
idmap config DOMAIN : backend = rid
```

c. Set a range that is big enough to include all RIDs that will be assigned in the future. For example:

```
idmap config DOMAIN : range = 2000000-2999999
```

Samba ignores users and groups whose RIDs in this domain are not within the range.

**IMPORTANT**

The range must not overlap with any other domain configuration on this server. For further details, see Section 15.1.5.3.1, “Planning ID Ranges”.

d. Set a shell and home directory path that will be assigned to all mapped users. For example:

```
template shell = /bin/bash
template homedir = /home/%U
```

For details about variable substitution, see the VARIABLE SUBSTITUTIONS section in the \textit{smb.conf} (5) man page.

2. Verify the /etc/samba/smb.conf file:

```
~\]# testparm
```

For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

3. Reload the Samba configuration:

```
~\]# smbcontrol all reload-config
```

4. Verify that the settings work as expected. See the section called “Verifying That the Operating System Can Retrieve Domain User Accounts and Groups”.

**15.1.5.4.4. Using the autorid ID Mapping Back End [2]**

The autorid back end works similar to the rid ID mapping back end, but can automatically assign IDs for different domains. This enables you to use the autorid back end in the following situations:

- Only for the * default domain.
For the * default domain and additional domains, without the need to create ID mapping configurations for each of the additional domains.

Only for specific domains.

15.1.5.4.4.1. Benefits and Drawbacks of Using the autorid Back End

Benefits

- All domain users and groups whose calculated UID and GID is within the configured range are automatically available on the domain member.
- You do not need to manually assign IDs, home directories, and login shells.
- No duplicate IDs, even if multiple objects in a multi-domain environment have the same RID.

Drawbacks

- User and group IDs are not the same across Samba domain members.
- All domain users get the same login shell and home directory assigned. However, you can use variables.
- You cannot exclude individual users or groups from being available on the domain member. Only users and groups whose calculated UID or GID is outside of the configured range are excluded.

15.1.5.4.4.2. Configuring the autorid Back End

To configure a Samba domain member to use the autorid ID mapping back end for the * default domain:

NOTE

If you use autorid for the default domain, adding additional ID mapping configuration for domains is optional.

Procedure 15.7. Configuring the autorid Back End on a Domain Member

1. Edit the [global] section in the /etc/samba/smb.conf file:

   a. Enable the autorid ID mapping back end for the * default domain:

   ```
   idmap config * : backend = autorid
   ```

   b. Set a range that is big enough to assign IDs for all existing and future objects. For example:

   ```
   idmap config * : range = 10000-999999
   ```

   Samba ignores users and groups whose calculated IDs in this domain are not within the range. For details about how the back end calculated IDs, see the THE MAPPING FORMULAS section in the idmap_autorid(8) man page.
WARNING

After you set the range and Samba starts using it, you can only increase the upper limit of the range. Any other change to the range can result in new ID assignments, and thus in losing file ownerships.

c. Optionally, set a range size. For example:

```bash
idmap config * : rangesize = 200000
```

Samba assigns this number of continuous IDs for each domain's object until all IDs from the range set in the `idmap config * : range` parameter are taken. For further details, see the `rangesize` parameter description in the `idmap_autorid(8)` man page.

d. Set a shell and home directory path that will be assigned to all mapped users. For example:

```bash
template shell = /bin/bash
template homedir = /home/%U
```

For details about variable substitution, see the `VARIABLE SUBSTITUTIONS` section in the `smb.conf(5)` man page.

e. Optionally, add additional ID mapping configuration for domains. If no configuration for an individual domain is available, Samba calculates the ID using the `autorid` back end settings in the previously configured `*` default domain.

```bash
~# testparm
```

For details, see Section 15.1.2, “Verifying the `smb.conf` File by Using the `testparm` Utility”.

3. Reload the Samba configuration:

```bash
~# smbcontrol all reload-config
```

4. Verify that the settings work as expected. See the section called “Verifying That the Operating System Can Retrieve Domain User Accounts and Groups”.

15.1.6. Integrating a Samba File Server Into an IdM Domain
If you run Red Hat Identity Management (IdM) and Samba in your environment, you can configure the Samba server to authenticate IdM users using Kerberos when they access a share.

For details, see the corresponding section in the Red Hat Windows Integration Guide.

### 15.1.7. Configuring File Shares on a Samba Server

To use Samba as a file server, add shares to the `/etc/samba/smb.conf` file of your standalone or domain member configuration.

You can add shares that uses either:

- POSIX ACLs. See Section 15.1.7.1, “Setting up a Share That Uses POSIX ACLs”.
- Fine-granular Windows ACLs. See Section 15.1.7.2, “Setting up a Share That Uses Windows ACLs”.

#### 15.1.7.1. Setting up a Share That Uses POSIX ACLs [3]

As a Linux service, Samba supports shares with POSIX ACLs. They enable you to manage permissions locally on the Samba server using utilities, such as `chmod`. If the share is stored on a file system that supports extended attributes, you can define ACLs with multiple users and groups.

**NOTE**

If you need to use fine-granular Windows ACLs instead, see Section 15.1.7.2, “Setting up a Share That Uses Windows ACLs”.

Before you can add a share, set up Samba. See:

- Section 15.1.4, “Setting up Samba as a Standalone Server”
- Section 15.1.5, “Setting up Samba as a Domain Member”

##### 15.1.7.1.1. Adding a Share That Uses POSIX ACLs

To create a share named `example`, that provides the content of the `/srv/samba/example/` directory, and uses POSIX ACLs:

**Procedure 15.8. Adding a Share That Uses POSIX ACLs**

1. Optionally, create the folder if it does not exist. For example:

   ```bash
   ~]# mkdir -p /srv/samba/example/
   ```

2. If you run SELinux in enforcing mode, set the `samba_share_t` context on the directory:

   ```bash
   ~]# semanage fcontext -a -t samba_share_t "/srv/samba/example(/.*)?"
   ~]# restorecon -Rv /srv/samba/example/
   ```

3. Set file system ACLs on the directory. For details, see Section 15.1.7.1.2, “Setting ACLs”.
4. Add the example share to the /etc/samba/smb.conf file. For example, to add the share write-enabled:

```plaintext
[example]
path = /srv/samba/example/
read only = no
```

**NOTE**
Regardless of the file system ACLs; if you do not set read only = no, Samba shares the directory in read-only mode.

5. Verify the /etc/samba/smb.conf file:

```
~]# testparm
```

For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

6. Open the required ports and reload the firewall configuration using the firewall-cmd utility:

```
~]# firewall-cmd --permanent --add-service=samba
~]# firewall-cmd --reload
```

7. Restart the smb service:

```
~]# systemctl restart smb
```

8. Optionally, enable the smb service to start automatically at boot time:

```
~]# systemctl enable smb
```

15.1.7.1.2. Setting ACLs

Shares that use POSIX ACLs support:

- Standard Linux ACLs. For details, see Section 15.1.7.1.2.1, “Setting Standard Linux ACLs”.
- Extended ACLs. For details, see Section 15.1.7.1.2.2, “Setting Extended ACLs”.

15.1.7.1.2.1. Setting Standard Linux ACLs

The standard ACLs on Linux support setting permissions for one owner, one group, and for all other undefined users. You can use the chown, chgrp, and chmod utility to update the ACLs. If you require precise control, then you use the more complex POSIX ACLs, see Section 15.1.7.1.2.2, “Setting Extended ACLs”.

For example, to set the owner of the /srv/samba/example/ directory to the root user, grant read and write permissions to the Domain Users group, and deny access to all other users:

```
~]# chown root:"Domain Users" /srv/samba/example/
~]# chmod 2770 /srv/samba/example/
```
NOTE

Enabling the set-group-ID (SGID) bit on a directory automatically sets the default group for all new files and subdirectories to that of the directory group, instead of the usual behavior of setting it to the primary group of the user who created the new directory entry.

For further details about permissions, see the chown(1) and chmod(1) man pages.

15.1.7.1.2.2. Setting Extended ACLs

If the file system the shared directory is stored on supports extended ACLs, you can use them to set complex permissions. Extended ACLs can contain permissions for multiple users and groups.

Extended POSIX ACLs enable you to configure complex ACLs with multiple users and groups. However, you can only set the following permissions:

- No access
- Read access
- Write access
- Full control

If you require the fine-granular Windows permissions, such as `create folder / append data`, configure the share to use Windows ACLs. See Section 15.1.7.2, “Setting up a Share That Uses Windows ACLs”.

To use extended POSIX ACLs on a share:

Procedure 15.9. Enabling Extended POSIX ACLs on a Share

1. Enable the following parameter in the share's section in the `/etc/samba/smb.conf` file to enable ACL inheritance of extended ACLs:

   ```
   inherit acls = yes
   ```

   For details, see the parameter description in the `smb.conf(5)` man page.

2. Restart the `smb` service:

   ```
   ~]# systemctl restart smb
   ```

3. Optionally, enable the `smb` service to start automatically at boot time:

   ```
   ~]# systemctl enable smb
   ```

4. Set the ACLs on the directory. For details about using extended ACLs, see Chapter 4, Access Control Lists.

   ```
   Example 15.4. Setting Extended ACLs
   ```
The following procedure sets read, write, and execute permissions for the **Domain Admins** group, read, and execute permissions for the **Domain Users** group, and deny access to everyone else on the /srv/samba/example/ directory:

**Procedure 15.10. Setting Extended ACLs**

1. Disable auto-granting permissions to the primary group of user accounts:

   ```
   ~
   # setfacl -m group::--- /srv/samba/example/
   ~
   # setfacl -m default:group::--- /srv/samba/example/
   ```

   The primary group of the directory is additionally mapped to the dynamic **CREATOR GROUP** principal. When you use extended POSIX ACLs on a Samba share, this principal is automatically added and you cannot remove it.

2. Set the permissions on the directory:

   a. Grant read, write, and execute permissions to the **Domain Admins** group:

   ```
   ~
   # setfacl -m group:"DOMAIN\Domain Admins":rwx /srv/samba/example/
   ```

   b. Grant read and execute permissions to the **Domain Users** group:

   ```
   ~
   # setfacl -m group:"DOMAIN\Domain Users":r-x /srv/samba/example/
   ```

   c. Set permissions for the **other** ACL entry to deny access to users that do not match the other ACL entries:

   ```
   ~
   # setfacl -R -m other::--- /srv/samba/example/
   ```

   These settings apply only to this directory. In Windows, these ACLs are mapped to the **This folder only** mode.

3. To enable the permissions set in the previous step to be inherited by new file system objects created in this directory:

   ```
   ~
   # setfacl -m default:group:"DOMAIN\Domain Admins":rwx /srv/samba/example/
   ~
   # setfacl -m default:group:"DOMAIN\Domain Users":r-x /srv/samba/example/
   ~
   # setfacl -m default:other::--- /srv/samba/example/
   ```

   With these settings, the **This folder only** mode for the principals is now set to **This folder, subfolders, and files**.

Samba maps the previously set permissions to the following Windows ACLs:

<table>
<thead>
<tr>
<th>Principal</th>
<th>Access</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DOMAIN\Domain Admins</strong></td>
<td>rwx</td>
<td>This folder, subfolders, and files</td>
</tr>
<tr>
<td><strong>DOMAIN\Domain Users</strong></td>
<td>r-x</td>
<td>This folder, subfolders, and files</td>
</tr>
<tr>
<td><strong>other</strong></td>
<td>---</td>
<td>This folder only</td>
</tr>
</tbody>
</table>
### Principal Access Applies to

<table>
<thead>
<tr>
<th>Principal</th>
<th>Access</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DOMAIN\Domain Admins</strong></td>
<td>Full control</td>
<td>This folder, subfolders, and files</td>
</tr>
<tr>
<td><strong>DOMAIN\Domain Users</strong></td>
<td>Read &amp; execute</td>
<td>This folder, subfolders, and files</td>
</tr>
<tr>
<td>Everyone [a]</td>
<td>None</td>
<td>This folder, subfolders, and files</td>
</tr>
<tr>
<td><strong>owner</strong> (Unix User\owner) [b]</td>
<td>Full control</td>
<td>This folder only</td>
</tr>
<tr>
<td><strong>primary_group</strong> (Unix User\primary_group) [c]</td>
<td>None</td>
<td>This folder only</td>
</tr>
<tr>
<td><strong>CREATOR OWNER</strong> [d] [e]</td>
<td>Full control</td>
<td>Subfolders and files only</td>
</tr>
<tr>
<td><strong>CREATOR GROUP</strong> [f] [e]</td>
<td>None</td>
<td>Subfolders and files only</td>
</tr>
</tbody>
</table>

[a] Samba maps the permissions for this principal from the other ACL entry.

[b] Samba maps the owner of the directory to this entry.

[c] Samba maps the primary group of the directory to this entry.

[d] On new file system objects, the creator inherits automatically the permissions of this principal.

[e] Configuring or removing these principals from the ACLs not supported on shares that use POSIX ACLs.

[f] On new file system objects, the creator's primary group inherits automatically the permissions of this principal.

### 15.1.7.1.3. Setting Permissions on a Share

Optionally, to limit or grant access to a Samba share, you can set certain parameters in the share's section in the `/etc/samba/smb.conf` file.

**NOTE**

Share-based permissions manage if a user, group, or host is able to access a share. These settings do not affect file system ACLs.

Use share-based settings to restrict access to shares. For example, to deny access from specific hosts.

### 15.1.7.1.3.1. Configuring User and Group-based Share Access
User and group-based access control enables you to grant or deny access to a share for certain users and groups. For example, to enable all members of the **Domain Users** group to access a share while access is denied for the **user** account, add the following parameters to the share's configuration:

```
valid users = +DOMAIN\"Domain Users"
invalid users = DOMAIN\user
```

The **invalid users** parameter has a higher priority than **valid users** parameter. For example, if the **user** account is a member of the **Domain Users** group, access is denied to this account when you use the previous example.

For further details, see the parameter descriptions in the smb.conf(5) man page.

### 15.1.7.1.3.2. Configuring Host-based Share Access

Host-based access control enables you to grant or deny access to a share based on client's host names, IP addresses, or IP ranges.

For example, to enable the **127.0.0.1** IP address, the **192.0.2.0/24** IP range, and the **client1.example.com** host to access a share, and additionally deny access for the **client2.example.com** host:

**Procedure 15.11. Configuring Host-based Share Access**

1. Add the following parameters to the configuration of the share in the `/etc/samba/smb.conf`:

   ```
   hosts allow = 127.0.0.1 192.0.2.0/24 client1.example.com
   hosts deny = client2.example.com
   ```

2. Reload the Samba configuration

   ```
   ~]# smbcontrol all reload-config
   ```

   The **hosts deny** parameter has a higher priority than **hosts allow**. For example, if **client1.example.com** resolves to an IP address that is listed in the **hosts allow** parameter, access for this host is denied.

   For further details, see the parameter description in the smb.conf(5) man page.

### 15.1.7.2. Setting up a Share That Uses Windows ACLs [4]

Samba supports setting Windows ACLs on shares and file system object. This enables you to:

- Use the fine-granular Windows ACLs
- Manage share permissions and file system ACLs using Windows

Alternatively, you can configure a share to use POSIX ACLs. For details, see Section 15.1.7.1, “Setting up a Share That Uses POSIX ACLs”.

### 15.1.7.2.1. Granting the SeDiskOperatorPrivilege Privilege
Only users and groups having the SeDiskOperatorPrivilege privilege granted can configure permissions on shares that use Windows ACLs. For example, to grant the privilege to the \Domain\Domain Admins group:

```bash
~]# net rpc rights grant "\Domain\Domain Admins" SeDiskOperatorPrivilege \-U "\Domain\administrator"
Enter \Domain\administrator's password:
Successfully granted rights.
```

**NOTE**

In a domain environment, grant SeDiskOperatorPrivilege to a domain group. This enables you to centrally manage the privilege by updating a user's group membership.

To list all users and groups having SeDiskOperatorPrivilege granted:

```bash
~]# net rpc rights list privileges SeDiskOperatorPrivilege \-U "\Domain\administrator"
Enter administrator's password:
SeDiskOperatorPrivilege:
    BUILTIN\Administrators
    \Domain\Domain Admins
```

### 15.1.7.2.2. Enabling Windows ACL Support

To configure shares that support Windows ACLs, you must enable this feature in Samba. To enable it globally for all shares, add the following settings to the [global] section of the /etc/samba/smb.conf file:

- `vfs objects = acl_xattr`
- `map acl inherit = yes`
- `store dos attributes = yes`

Alternatively, you can enable Windows ACL support for individual shares, by adding the same parameters to a share's section instead.

#### 15.1.7.2.3. Adding a Share That Uses Windows ACLs

To create a share named example, that shares the content of the /srv/samba/example/ directory, and uses Windows ACLs:

**Procedure 15.12. Adding a Share That Uses Windows ACLs**

1. Optionally, create the folder if it does not exists. For example:

   ```bash
   ~]# mkdir -p /srv/samba/example/
   ```

2. If you run SELinux in enforcing mode, set the samba_share_t context on the directory:

   ```bash
   ~]# semanage fcontext -a -t samba_share_t "/srv/samba/example(/.*)?"
   ~]# restorecon -Rv /srv/samba/example/
   ```
3. Add the example share to the /etc/samba/smb.conf file. For example, to add the share write-enabled:

   [example]
   path = /srv/samba/example/
   read only = no

   **NOTE**

   Regardless of the file system ACLs; if you do not set read only = no, Samba shares the directory in read-only mode.

4. If you have not enabled Windows ACL support in the [global] section for all shares, add the following parameters to the [example] section to enable this feature for this share:

   vfs objects = acl_xattr
   map acl inherit = yes
   store dos attributes = yes

5. Verify the /etc/samba/smb.conf file:

   ~# testparm

   For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

6. Open the required ports and reload the firewall configuration using the firewall-cmd utility:

   ~# firewall-cmd --permanent --add-service=samba
   ~# firewall-cmd --reload

7. Restart the smb service:

   ~# systemctl restart smb

8. Optionally, enable the smb service to start automatically at boot time:

   ~# systemctl enable smb

15.1.7.2.4. Managing Share Permissions and File System ACLs of a Share That Uses Windows ACLs

To manage share and file system ACLs on a Samba share that uses Windows ACLs, use a Windows applications, such as Computer Management. For details, see your Windows documentation.

Alternatively, use the smbcaccls utility to manage ACLs. For details, see Section 15.1.7.3, “Managing ACLs on an SMB Share Using smbcaccls”.

NOTE

To modify the file system permissions from Windows, you must use an account that has the \texttt{SeDiskOperatorPrivilege} privilege granted. See \textit{Section 15.1.7.2.1, “Granting the \texttt{SeDiskOperatorPrivilege} Privilege”}.

15.1.7.3. Managing ACLs on an SMB Share Using \texttt{smbcacls}

The \texttt{smbcacls} utility can list, set, and delete ACLs of files and directories stored on an SMB share. You can use \texttt{smbcacls} to manage file system ACLs:

- On a local or remote Samba server that uses advanced Windows ACLs or POSIX ACLs.
- On Red Hat Enterprise Linux to remotely manage ACLs on a share hosted on Windows.

15.1.7.3.1. Understanding Access Control Entries

Each ACL entry of a file system object contains Access Control Entries (ACE) in the following format:

\begin{verbatim}
security_principal:access_right/inheritance_information/permissions
\end{verbatim}

\textbf{Example 15.5. Access Control Entries}

If the \texttt{AD\Domain Users} group has \texttt{Modify} permissions that apply to \texttt{This} folder, subfolders, and files on Windows, the ACL contains the following ACEs:

\begin{verbatim}
AD\Domain Users:ALLOWED/OI|CI/CHANGE
\end{verbatim}

The following describes the individual ACEs:

\textbf{Security principal}

The security principal is the user, group, or SID the permissions in the ACL are applied to.

\textbf{Access right}

Defines if access to an object is granted or denied. The value can be \texttt{ALLOWED} or \texttt{DENIED}.

\textbf{Inheritance information}

The following values exist:

\textbf{Table 15.3. Inheritance Settings}

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Maps to</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI</td>
<td>Object Inherit</td>
<td>This folder and files</td>
</tr>
<tr>
<td>CI</td>
<td>Container Inherit</td>
<td>This folder and subfolders</td>
</tr>
<tr>
<td>IO</td>
<td>Inherit Only</td>
<td>The ACE does not apply to the current file or directory.</td>
</tr>
</tbody>
</table>
Additionally, the values can be combined as follows:

### Table 15.4. Inheritance Settings Combinations

<table>
<thead>
<tr>
<th>Value Combinations</th>
<th>Maps to the Windows Applies to Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI</td>
<td>CI</td>
</tr>
<tr>
<td>OI</td>
<td>CI</td>
</tr>
<tr>
<td>CI</td>
<td>IO</td>
</tr>
<tr>
<td>OI</td>
<td>IO</td>
</tr>
</tbody>
</table>

**Permissions**

This value can be either a hex value that represents one or more Windows permissions or an `smbcacls` alias:

- A hex value that represents one or more Windows permissions.

The following table displays the advanced Windows permissions and their corresponding value in hex format:

### Table 15.5. Windows Permissions and Their Corresponding `smbcacls` Value in Hex Format

<table>
<thead>
<tr>
<th>Windows Permissions</th>
<th>Hex Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full control</td>
<td>0x001F01FF</td>
</tr>
<tr>
<td>Traverse folder / execute file</td>
<td>0x00100020</td>
</tr>
<tr>
<td>List folder / read data</td>
<td>0x00100001</td>
</tr>
<tr>
<td>Read attributes</td>
<td>0x00100080</td>
</tr>
<tr>
<td>Read extended attributes</td>
<td>0x00100008</td>
</tr>
<tr>
<td>Create files / write data</td>
<td>0x00100002</td>
</tr>
<tr>
<td>Create folders / append data</td>
<td>0x00100004</td>
</tr>
<tr>
<td>Write attributes</td>
<td>0x00100100</td>
</tr>
</tbody>
</table>
Write extended attributes 0x00100010
Delete subfolders and files 0x00100040
Delete 0x00110000
Read permissions 0x00120000
Change permissions 0x00140000
Take ownership 0x00180000

Multiple permissions can be combined as a single hex value using the bit-wise OR operation. For details, see Section 15.1.7.3.3, “Calculating an ACE Mask”.

- An `smbcacls` alias. The following table displays the available aliases:

**Table 15.6. Existing smbcacls Aliases and Their Corresponding Windows Permission**

<table>
<thead>
<tr>
<th>smbcacls Alias</th>
<th>Maps to Windows Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
</tr>
<tr>
<td>READ</td>
<td>Read &amp; execute</td>
</tr>
<tr>
<td>W</td>
<td>Special</td>
</tr>
<tr>
<td></td>
<td>Create files / write data</td>
</tr>
<tr>
<td></td>
<td>Create folders / append data</td>
</tr>
<tr>

<td>Delete</td>
</tr>
<tr>
<td>P</td>
<td>Change permissions</td>
</tr>
<tr>
<td>O</td>
<td>Take ownership</td>
</tr>
<tr>
<td>X</td>
<td>Traverse / execute</td>
</tr>
<tr>
<td>CHANGE</td>
<td>Modify</td>
</tr>
</tbody>
</table>
### 15.1.7.3.2. Displaying ACLs Using `smbcacls`

If you run `smbcacls` without any operation parameter, such as `--add`, the utility displays the ACLs of a file system object.

For example, to list the ACLs of the root directory of the `//server/example` share:

```
~]# smbcacls //server/example / -U "DOMAIN\administrator"
Enter DOMAIN\administrator's password:
REVISION:1
CONTROL:SR|PD|DI|DP
OWNER:AD\Administrators
GROUP:AD\Domain Users
ACL:AD\Administrator:ALLOWED/OI|CI/FULL
ACL:AD\Domain Users:ALLOWED/OI|CI/CHANGE
ACL:AD\Domain Guests:ALLOWED/OI|CI/0x00100021
```

The output of the command displays:

- **REVISION**: The internal Windows NT ACL revision of the security descriptor
- **CONTROL**: Security descriptor control
- **OWNER**: Name or SID of the security descriptor's owner
- **GROUP**: Name or SID of the security descriptor's group
- **ACL entries. For details, see Section 15.1.7.3.1, “Understanding Access Control Entries”.

### 15.1.7.3.3. Calculating an ACE Mask

In most situations, when you add or update an ACE, you use the `smbcacls` aliases listed in Table 15.6, “Existing `smbcacls` Aliases and Their Corresponding Windows Permission”.

However, if you want to set advanced Windows permissions as listed in Table 15.5, “Windows Permissions and Their Corresponding `smbcacls` Value in Hex Format”, you must use the bit-wise **OR** operation to calculate the correct value. You can use the following shell command to calculate the value:

```
~]# echo $(printf '0x%X' $(($hex_value_1 | $hex_value_2 | ... )))
```
Example 15.6. Calculating an ACE Mask

You want to set the following permissions:

- Traverse folder / execute file (0x00100020)
- List folder / read data (0x00100001)
- Read attributes (0x00100080)

To calculate the hex value for the previous permissions, enter:

```bash
~]# echo $(printf '0x%X' $(( 0x00100020 | 0x00100001 | 0x00100080 )))
0x1000A1
```

Use the returned value when you set or update an ACE.

15.1.7.3.4. Adding, Updating, And Removing an ACL Using `smbcacls`

Depending on the parameter you pass to the `smbcacls` utility, you can add, update, and remove ACLs from a file or directory.

**Adding an ACL**

To add an ACL to the root of the `//server/example` share that grants `CHANGE` permissions for *This folder, subfolders, and files* to the `AD\Domain Users` group:

```bash
~]# smbcacls //server/example / -U "DOMAIN\administrator \ --add ACL:"AD\Domain Users":ALLOWED/OI|CI/CHANGE
```

**Updating an ACL**

Updating an ACL is similar to adding a new ACL. You update an ACL by overriding the ACL using the `-modify` parameter with an existing security principal. If `smbcacls` finds the security principal in the ACL list, the utility updates the permissions. Otherwise, the command fails with an error:

ACL for SID principal_name not found

For example, to update the permissions of the `AD\Domain Users` group and set them to `READ` for *This folder, subfolders, and files*:

```bash
~]# smbcacls //server/example / -U "DOMAIN\administrator \ --modify ACL:"AD\Domain Users":ALLOWED/OI|CI/CHANGE
```

**Deleting an ACL**

To delete an ACL, pass the `-delete` with the exact ACL to the `smbcacls` utility. For example:

```bash
~]# smbcacls //server/example / -U "DOMAIN\administrator \ --delete ACL:"AD\Domain Users":ALLOWED/OI|CI/READ
```

15.1.7.4. Enabling Users to Share Directories on a Samba Server

On a Samba server, you can configure that users can share directories without `root` permissions.
15.1.7.4.1. Enabling the User Shares Feature

Before users can share directories, the administrator must enable user shares in Samba. For example, to enable only members of the local example group to create user shares:

Procedure 15.13. Enabling User Shares

1. Create the local example group, if it does not exist:
   ```
   ~
   # groupadd example
   ```

2. Prepare the directory for Samba to store the user share definitions and set its permissions properly. For example:
   a. Create the directory:
   ```
   ~
   # mkdir -p /var/lib/samba/usershares/
   ```
   b. Set write permissions for the example group:
   ```
   ~
   # chgrp example /var/lib/samba/usershares/
   ~
   # chmod 1770 /var/lib/samba/usershares/
   ```
   Set the sticky bit to prevent users to rename or delete files stored by other users in this directory.

3. Edit the /etc/samba/smb.conf file and add the following to the [global] section:
   a. Set the path to the directory you configured to store the user share definitions. For example:
   ```
   usershare path = /var/lib/samba/usershares/
   ```
   b. Set how many user shares Samba allows to be created on this server. For example:
   ```
   usershare max shares = 100
   ```
   If you use the default of 0 for the usershare max shares parameter, user shares are disabled.
   c. Optionally, set a list of absolute directory paths. For example, to configure that Samba only allows to share subdirectories of the /data and /srv directory to be shared, set:
   ```
   usershare prefix allow list = /data /srv
   ```
   For a list of further user share-related parameters you can set, see the USERSHARES section in the smb.conf(5) man page.

4. Verify the /etc/samba/smb.conf file:
   ```
   ~
   # testparm
   ```
   For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.
5. Reload the Samba configuration:

```bash
~]# smbcontrol all reload-config
```

Users are now able to create user shares. For details, see Section 15.1.7.4.2, “Adding a User Share”.

### 15.1.7.4.2. Adding a User Share

After you configured Samba according to Section 15.1.7.4.1, “Enabling the User Shares Feature”, users can share directories on the Samba server without root permissions by running the `net usershare add` command.

**Synopsis of the `net usershare add` command:**

```bash
net usershare add share_name path [[ comment ] | [ ACLs ]] [ guest_ok=y|n ]
```

**IMPORTANT**

If you set ACLs when you create a user share, you must specify the comment parameter prior to the ACLs. To set an empty comment, use an empty string in double quotes.

Note that users can only enable guest access on a user share, if the administrator set `usershare allow guests = yes` in the `[global]` section in the `/etc/samba/smb.conf` file.

**Example 15.7. Adding a User Share**

A user wants to share the `/srv/samba/` directory on a Samba server. The share should be named `example`, have no comment set, and should be accessible by guest users. Additionally, the share permissions should be set to full access for the `AD\Domain Users` group and read permissions for other users. To add this share, run as the user:

```bash
~]$ net usershare add example /srv/samba/ "" \
    "AD\Domain Users":F,Everyone:R guest_ok=yes
```

### 15.1.7.4.3. Updating Settings of a User Share

If you want to update settings of a user share, override the share by using the `net usershare add` command with the same share name and the new settings. See Section 15.1.7.4.2, “Adding a User Share”.

### 15.1.7.4.4. Displaying Information About Existing User Shares

Users can enter the `net usershare info` command on a Samba server to display user shares and their settings.

To display all user shares created by any user:

```bash
~]$ net usershare info -l
[share_1] 
path=/srv/samba/
```
To list only shares created by the user who runs the command, omit the `\-l` parameter.

To display only the information about specific shares, pass the share name or wild cards to the command. For example, to display the information about shares whose name starts with `share_`:

```bash
~$ net usershare info -l share_*
```

15.1.7.4.5. Listing User Shares

If you want to list only the available user shares without their settings on a Samba server, use the `net usershare list` command.

To list the shares created by any user:

```bash
~$ net usershare list -l
share_1
share_2
...
```

To list only shares created by the user who runs the command, omit the `\-l` parameter.

To list only specific shares, pass the share name or wild cards to the command. For example, to list only shares whose name starts with `share_`:

```bash
~$ net usershare list -l share_*
```

15.1.7.4.6. Deleting a User Share

To delete a user share, enter as the user who created the share or as the root user:

```bash
~$ net usershare delete share_name
```

15.1.7.5. Enabling Guest Access to a Share

In certain situations, you want to share a directory to which users can connect without authentication. To configure this, enable guest access on a share.

**WARNING**

Shares that do not require authentication can be a security risk.
If guest access is enabled on a share, Samba maps guest connections to the operating system account set in the `guest account` parameter. Guest users can access these files if at least one of the following conditions is satisfied:

- The account is listed in file system ACLs
- The POSIX permissions for other users allow it

**Example 15.8. Guest Share Permissions**

If you configured Samba to map the guest account to `nobody`, which is the default, the ACLs in the following example:

- Allow guest users to read `file1.txt`
- Allow guest users to read and modify `file2.txt`.
- Prevent guest users to read or modify `file3.txt`

```
-rw-r--r--. 1 root      root      1024 1. Sep 10:00 file1.txt
-rw-r-----.. 1 nobody   root      1024 1. Sep 10:00 file2.txt
-rw-r-----.. 1 root      root      1024 1. Sep 10:00 file3.txt
```

For example, to enable guest access for the existing `[example]` share:

**Procedure 15.14. Setting up a Guest Share**

1. Edit the `/etc/samba/smb.conf` file:
   a. If this is the first guest share you set up on this server:
      i. Set `map to guest = Bad User` in the `[global]` section:

      ```
      [global]
      ...
      map to guest = Bad User
      ```

      With this setting, Samba rejects login attempts that use an incorrect password unless the user name does not exist. If the specified user name does not exist and guest access is enabled on a share, Samba treats the connection as a guest log in.

      ii. By default, Samba maps the guest account to the `nobody` account on Red Hat Enterprise Linux. Optionally, you can set a different account. For example:

      ```
      [global]
      ...
      guest account = user_name
      ```

      The account set in this parameter must exist locally on the Samba server. For security reasons, Red Hat recommends using an account that does not have a valid shell assigned.

   b. Add the `guest ok = yes` setting to the `[example]` section:
2. Verify the /etc/samba/smb.conf file:

~

Verify the /etc/samba/smb.conf file:

~

For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

3. Reload the Samba configuration:

~

15.1.8. Setting up a Samba Print Server

If you set up Samba as a print server, clients in your network can use Samba to print. Additionally, Windows clients can, if configured, download the driver from the Samba server.

Before you can share a printer, set up Samba:

- Section 15.1.4, “Setting up Samba as a Standalone Server”
- Section 15.1.5, “Setting up Samba as a Domain Member”

15.1.8.1. The Samba spoolssd Service

The Samba spoolssd is a service that is integrated into the smbd service. Enable spoolssd in the Samba configuration to significantly increase the performance on print servers with a high number of jobs or printers.

Without spoolssd, Samba forks the smbd process and initializes the printcap cache for each print job. In case of a large number of printers, the smbd service can become unresponsive for multiple seconds while the cache is initialized. The spoolssd service enables you to start pre-forked smbd processes that are processing print jobs without any delays. The main spoolssd smbd process uses a low amount of memory, and forks and terminates child processes.

To enable the spoolssd service:

Procedure 15.15. Enabling the spoolssd Service

1. Edit the [global] section in the /etc/samba/smb.conf file:

   a. Add the following parameters:

   ```
   rpc_server:spoolss = external
   rpc_daemon:spoolssd = fork
   ```

   b. Optionally, you can set the following parameters:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spoolssd:prefork_min_children</td>
<td>5</td>
<td>Minimum number of child processes</td>
</tr>
<tr>
<td>spoolssd:prefork_max_children</td>
<td>25</td>
<td>Maximum number of child processes</td>
</tr>
<tr>
<td>spoolssd:prefork_spawn_rate</td>
<td>5</td>
<td>Samba forks the number of new child processes set in this parameter, up to the value set in <code>spoolssd:prefork_max_children</code>, if a new connection is established</td>
</tr>
<tr>
<td>spoolssd:prefork_max_allowed_clients</td>
<td>100</td>
<td>Number of clients, a child process serves</td>
</tr>
<tr>
<td>spoolssd:prefork_child_min_life</td>
<td>60</td>
<td>Minimum lifetime of a child process in seconds. 60 seconds is the minimum.</td>
</tr>
</tbody>
</table>

2. Verify the `/etc/samba/smb.conf` file:

```
~$ testparm
```

For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

3. Restart the `smb` service:

```
~$ systemctl restart smb
```

After you restarted the service, Samba automatically starts `smbd` child processes:

```
~$ ps axf
...
30903  smbd
30912   __ smbd
30913     __ smbd
30914     __ smbd
30915     __ smbd
...
```

### 15.1.8.2. Enabling Print Server Support in Samba

To enable the print server support:

**Procedure 15.16. Enabling Print Server Support in Samba**

1. On the Samba server, set up CUPS and add the printer to the CUPS back end. For details, see Section 15.3, “Print Settings”.
Samba can only forward the print jobs to CUPS if CUPS is installed locally on the Samba print server.

2. Edit the `/etc/samba/smb.conf` file:
   
   a. If you want to enable the `spoolssd` service, add the following parameters to the `[global]` section:
      
      ```
      rpc_server:spoolss = external
      rpc_daemon:spoolssd = fork
      ```
      
      For further details, see Section 15.1.8.1, “The Samba spoolssd Service”.
   
   b. To configure the printing back end, add the `[printers]` section:
      
      ```
      [printers]
      comment = All Printers
      path = /var/tmp/
      printable = yes
      create mask = 0600
      ```

      **IMPORTANT**
      
      The `printers` share name is hard-coded and cannot be changed.

3. Verify the `/etc/samba/smb.conf` file:
   
   ```
   ~# testparm
   ```
   
   For details, see Section 15.1.2, “Verifying the `smb.conf` File by Using the `testparm` Utility”.

4. Open the required ports and reload the firewall configuration using the `firewall-cmd` utility:
   
   ```
   ~# firewall-cmd --permanent --add-service=samba
   ~# firewall-cmd --reload
   ```

5. Restart the `smb` service:
   
   ```
   ~# systemctl restart smb
   ```
   
   After restarting the service, Samba automatically shares all printers that are configured in the CUPS back end. If you want to manually share only specific printers, see Section 15.1.8.3, “Manually Sharing Specific Printers”.

### 15.1.8.3. Manually Sharing Specific Printers

If you configured Samba as a print server, by default, Samba shares all printers that are configured in the CUPS back end. To share only specific printers:
Procedure 15.17. Manually Sharing a Specific Printer

1. Edit the `/etc/samba/smb.conf` file:
   
a. In the `[global]` section, disable automatic printer sharing by setting:
   
   ```
   load printers = no
   ```
   
b. Add a section for each printer you want to share. For example, to share the printer named `example` in the CUPS back end as `Example-Printer` in Samba, add the following section:
   
   ```
   [Example-Printer]
   path = /var/tmp/
   printable = yes
   printer name = example
   ```
   
   You do not need individual spool directories for each printer. You can set the same spool directory in the `path` parameter for the printer as you set in the `[printers]` section.

2. Verify the `/etc/samba/smb.conf` file:

   ```
   ~]# testparm
   ```

   For details, see Section 15.1.2, “Verifying the `smb.conf` File by Using the `testparm` Utility”.

3. Reload the Samba configuration:

   ```
   ~]# smbcontrol all reload-config
   ```

15.1.8.4. Setting up Automatic Printer Driver Downloads for Windows Clients

If you are running a Samba print server for Windows clients, you can upload drivers and preconfigure printers. If a user connects to a printer, Windows automatically downloads and installs the driver locally on the client. The user does not require local administrator permissions for the installation. Additionally, Windows applies preconfigured driver settings, such as the number of trays.

**NOTE**

Before setting up automatic printer driver download, must configure Samba as a print server and share a printer. For details, see Section 15.1.8, “Setting up a Samba Print Server”.

15.1.8.4.1. Basic Information about Printer Drivers

This section provides general information about printer drivers.

**Supported Driver Model Version**

Samba only supports the printer driver model version 3 which is supported in Windows 2000 and later, and Windows Server 2000 and later. Samba does not support the driver model version 4, introduced in Windows 8 and Windows Server 2012. However, these and later Windows versions also support version 3 drivers.
Package-aware Drivers
Samba does not support package-aware drivers.

Preparing a Printer Driver for Being Uploaded
Before you can upload a driver to a Samba print server:

- Unpack the driver if it is provided in a compressed format.
- Some drivers require to start a setup application that installs the driver locally on a Windows host. In certain situations, the installer extracts the individual files into the operating system’s temporary folder during the setup runs. To use the driver files for uploading:
  1. Start the installer.
  2. Copy the files from the temporary folder to a new location.
  3. Cancel the installation.

Ask your printer manufacturer for drivers that support uploading to a print server.

Providing 32-bit and 64-bit Drivers for a Printer to a Client
To provide the driver for a printer for both 32-bit and 64-bit Windows clients, you must upload a driver with exactly the same name for both architectures. For example, if you are uploading the 32-bit driver named Example PostScript and the 64-bit driver named Example PostScript (v1.0), the names do not match. Consequently, you can only assign one of the drivers to a printer and the driver will not be available for both architectures.

15.1.8.4.2. Enabling Users to Upload and Preconfigure Drivers
To be able to upload and preconfigure printer drivers, a user or a group needs to have the SePrintOperatorPrivilege privilege granted. For example, to grant the privilege to the printadmin group:

```bash
~~~
~]# net rpc rights grant "printadmin" SePrintOperatorPrivilege \ 
    -U "DOMAIN\administrator"
Enter DOMAIN\administrator's password:
Successfully granted rights.
```

NOTE
In a domain environment, grant SePrintOperatorPrivilege to a domain group. This enables you to centrally manage the privilege by updating a user’s group membership.

To list all users and groups having SePrintOperatorPrivilege granted:

```bash
~~~
~]# net rpc rights list privileges SePrintOperatorPrivilege \ 
    -U "DOMAIN\administrator"
Enter administrator's password:
SePrintOperatorPrivilege:
    BUILTIN\Administrators
    DOMAIN\printadmin
```

15.1.8.4.3. Setting up the print$ Share
Windows operating systems download printer drivers from a share named `print$` from a print server. This share name is hard-coded in Windows and cannot be changed.

To share the `/var/lib/samba/drivers/` directory as `print$`, and enable members of the local `printadmin` group to upload printer drivers:

### Procedure 15.18. Setting up the `print$` Share

1. Add the `[print$]` section to the `/etc/samba/smb.conf` file:

   ```
   [print$]
   path = /var/lib/samba/drivers/
   read only = no
   write list = @printadmin
   force group = @printadmin
   create mask = 0664
   directory mask = 2775
   ```

   Using these settings:
   - Only members of the `printadmin` group can upload printer drivers to the share.
   - The group of new created files and directories will be set to `printadmin`.
   - The permissions of new files will be set to 664.
   - The permissions of new directories will be set to 2775.

2. To upload only 64-bit drivers for a printer, include this setting in the `[global]` section in the `/etc/samba/smb.conf` file:

   ```
   spoolss: architecture = Windows x64
   ```

   Without this setting, Windows only displays drivers for which you have uploaded at least the 32-bit version.

3. Verify the `/etc/samba/smb.conf` file:

   ```
   ~]# testparm
   ```

   For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

4. Reload the Samba configuration

   ```
   ~]# smbcontrol all reload-config
   ```

5. Create the `printadmin` group if it does not exists:

   ```
   ~]# groupadd printadmin
   ```

6. Grant the `SePrintOperatorPrivilege` privilege to the `printadmin` group.

   ```
   ~]# net rpc rights grant "printadmin" SePrintOperatorPrivilege \
   ```
For further details, see Section 15.1.8.4.2, “Enabling Users to Upload and Preconfigure Drivers”.

7. If you run SELinux in enforcing mode, set the `samba_share_t` context on the directory:

```bash
~$ semanage fcontext -a -t samba_share_t
"/var/lib/samba/drivers(/.*)?"
~$ restorecon -Rv /var/lib/samba/drivers/
```

8. Set the permissions on the `/var/lib/samba/drivers/` directory:

- If you use POSIX ACLs, set:
  ```bash
  ~$ chgrp -R "printadmin" /var/lib/samba/drivers/
  ~$ chmod -R 2775 /var/lib/samba/drivers/
  ```

- If you use Windows ACLs, set:

<table>
<thead>
<tr>
<th>Principal</th>
<th>Access</th>
<th>Apply to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creator Owner</td>
<td>Full control</td>
<td>Subfolders and files only</td>
</tr>
<tr>
<td>Authenticated Users</td>
<td>Read &amp; execute, List folder contents, Read</td>
<td>This folder, subfolders and files</td>
</tr>
<tr>
<td>printadmin</td>
<td>Full control</td>
<td>This folder, subfolders and files</td>
</tr>
</tbody>
</table>

For details about setting ACLs on Windows, see your Windows documentation.

### 15.1.8.4.4. Creating a GPO to Enable Clients to Trust the Samba Print Server

For security reasons, recent Windows operating systems prevent clients from downloading non-package-aware printer drivers from an untrusted server. If your print server is a member in an AD, you can create a Group Policy Object (GPO) in your domain to trust the Samba server.

To create GPOs, the Windows computer you are using must have the Windows Remote Server Administration Tools (RSAT) installed. For details, see your Windows documentation.

**Procedure 15.19. Creating a GPO to Enable Clients to Trust the Samba Print Server**

1. Log into a Windows computer using an account that is allowed to edit group policies, such as the AD domain Administrator user.

2. Open the Group Policy Management Console.

3. Right-click to your AD domain and select **Create a GPO in this domain, and Link it here**
4. Enter a name for the GPO, such as **Legacy printer Driver Policy** and click **OK**. The new GPO will be displayed under the domain entry.

5. Right-click to the newly-created GPO and select **Edit** to open the **Group Policy Management Editor**.

6. Navigate to **Computer Configuration → Policies → Administrative Templates → Printers**.

7. On the right side of the window, double-click **Point and Print Restriction** to edit the policy:

   a. Enable the policy and set the following options:
      
      i. **Select Users can only point and print to these servers** and enter the fully-qualified domain name (FQDN) of the Samba print server to the field next to this option.

      ii. In both check boxes under **Security Prompts**, select **Do not show warning or elevation prompt**.
b. Click OK.

8. Double-click Package Point and Print - Approved servers to edit the policy:

   a. Enable the policy and click the Show button.

   b. Enter the FQDN of the Samba print server.
c. Close both the **Show Contents** and policy properties window by clicking **OK**.

9. Close the **Group Policy Management Editor**.

10. Close the **Group Policy Management** Console.

After the Windows domain members applied the group policy, printer drivers are automatically downloaded from the Samba server when a user connects to a printer.

For further details about using group policies, see your Windows documentation.

15.1.8.4.5. Uploading Drivers and Preconfiguring Printers

Use the **Print Management** application on a Windows client to upload drivers and preconfigure printers hosted on the Samba print server. For further details, see your Windows documentation.

15.1.9. Tuning the Performance of a Samba Server

This section describes what settings can improve the performance of Samba in certain situations, and which settings can have a negative performance impact.

15.1.9.1. Setting the SMB Protocol Version

Each new SMB version adds features and improves the performance of the protocol. The recent Windows and Windows Server operating systems always supports the latest protocol version. If Samba also uses the latest protocol version, Windows clients connecting to Samba benefit from the performance improvements. In Samba, the default value of the **server max protocol** is set to the latest supported stable SMB protocol version.

To always have the latest stable SMB protocol version enabled, do not set the **server max protocol** parameter. If you set the parameter manually, you will need to modify the setting with each new version of the SMB protocol, to have the latest protocol version enabled.

To unset, remove the **server max protocol** parameter from the **[global]** section in the **/etc/samba/smb.conf** file.

15.1.9.2. Tuning Shares with Directories That Contain a Large Number of Files
To improve the performance of shares that contain directories with more than 100,000 files:

Procedure 15.20. Tuning Shares with Directories That Contain a Large Number of Files

1. Rename all files on the share to lowercase.

   NOTE
   Using the settings in this procedure, files with names other than in lowercase will no longer be displayed.

2. Set the following parameters in the share's section:

   ```
   case sensitive = true
   default case = lower
   preserve case = no
   short preserve case = no
   ```

   For details about the parameters, see their descriptions in the `smb.conf` man page.

3. Reload the Samba configuration:

   ```
   ~]# smbcontrol all reload-config
   ```

   After you applied these settings, the names of all newly created files on this share use lowercase. Because of these settings, Samba no longer needs to scan the directory for uppercase and lowercase, which improves the performance.

15.1.9.3. Settings That Can Have a Negative Performance Impact

By default, the kernel in Red Hat Enterprise Linux is tuned for high network performance. For example, the kernel uses an auto-tuning mechanism for buffer sizes. Setting the `socket options` parameter in the `/etc/samba/smb.conf` file overrides these kernel settings. As a result, setting this parameter decreases the Samba network performance in most cases.

To use the optimized settings from the Kernel, remove the `socket options` parameter from the `[global]` section in the `/etc/samba/smb.conf`.

15.1.10. Frequently Used Samba Command-line Utilities

This section describes frequently used commands when working with a Samba server.

15.1.10.1. Using the `net` Utility

The `net` utility enables you to perform several administration tasks on a Samba server. This section describes the most frequently used subcommands of the `net` utility.

For further details, see the `net(8)` man page.

15.1.10.1.1. Using the `net ads join` and `net rpc join` Commands
Using the `join` subcommand of the `net` utility, you can join Samba to an AD or NT4 domain. To join the domain, you must create the `/etc/samba/smb.conf` file manually, and optionally update additional configurations, such as PAM.

**IMPORTANT**

Red Hat recommends using the `realm` utility to join a domain. The `realm` utility automatically updates all involved configuration files. For details, see Section 15.1.5.1, “Joining a Domain”.

To join a domain using the `net` command:

**Procedure 15.21. Joining a Domain Using the net Command**

1. Manually create the `/etc/samba/smb.conf` file with the following settings:
   - For an AD domain member:
     
     ```
     [global]
     workgroup = domain_name
     security = ads
     passdb backend = tdb
     realm = AD_REALM
     ```
   - For an NT4 domain member:
     
     ```
     [global]
     workgroup = domain_name
     security = user
     passdb backend = tdb
     ```

2. Add an ID mapping configuration for the * default domain and for the domain you want to join to the `[global]` section in the `/etc/samba/smb.conf`. For details, see Section 15.1.5.3, “Understanding ID Mapping”.

3. Verify the `/etc/samba/smb.conf` file:
   
   ```
   ~]# testparm
   ```
   For details, see Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

4. Join the domain as the domain administrator:
   - To join an AD domain:
     
     ```
     ~]# net ads join -U "DOMAIN\administrator"
     ```
   - To join an NT4 domain:
     
     ```
     ~]# net rpc join -U "DOMAIN\administrator"
     ```
5. Append the `winbind` source to the `passwd` and `group` database entry in the `/etc/nsswitch.conf` file:

```
passwd:     files winbind
group:      files winbind
```

6. Enable and start the `winbind` service:

```
~]# systemctl enable winbind
~]# systemctl start winbind
```

7. Optionally, configure PAM using the `authconf` utility.

   For details, see the Using Pluggable Authentication Modules (PAM) section in the _Red Hat System-Level Authentication Guide_.

8. Optionally for AD environments, configure the Kerberos client.

   For details, see the Configuring a Kerberos Client section in the _Red Hat System-Level Authentication Guide_.

### 15.1.10.1.2. Using the `net rpc rights` Command

In Windows, you can assign privileges to accounts and groups to perform special operations, such as setting ACLs on a share or upload printer drivers. On a Samba server, you can use the `net rpc rights` command to manage privileges.

#### Listing Privileges

To list all available privileges and their owners, use the `net rpc rights list` command. For example:

```
net rpc rights list -U "DOMAIN\administrator"
```

Enter `DOMAIN\administrator`'s password:

```
SeMachineAccountPrivilege  Add machines to domain
SeTakeOwnershipPrivilege  Take ownership of files or other objects
SeBackupPrivilege  Back up files and directories
SeRestorePrivilege  Restore files and directories
SeRemoteShutdownPrivilege  Force shutdown from a remote system
SePrintOperatorPrivilege  Manage printers
SeAddUsersPrivilege  Add users and groups to the domain
SeDiskOperatorPrivilege  Manage disk shares
SeSecurityPrivilege  System security
```

#### Granting Privileges

To grant a privilege to an account or group, use the `net rpc rights grant` command.

For example, grant the `SePrintOperatorPrivilege` privilege to the `DOMAIN\printadmin` group:

```
~]# net rpc rights grant "DOMAIN\printadmin" SePrintOperatorPrivilege \
-U "DOMAIN\administrator"
```

Enter `DOMAIN\administrator`'s password:

Successfully granted rights.
**Revoking Privileges**

To revoke a privilege from an account or group, use the `net rpc rights revoke`.

For example, to revoke the `SePrintOperatorPrivilege` privilege from the `DOMAIN\printadmin` group:

```
~\]# net rpc rights remoke "DOMAIN\printadmin" SePrintOperatorPrivilege \
-U "DOMAIN\administrator"
```

```
Enter DOMAIN\administrator's password:
Successfully revoked rights.
```

**15.10.1.3. Using the net rpc share Command**

The `net rpc share` command provides the capability to list, add, and remove shares on a local or remote Samba or Windows server.

**Listing Shares**

To list the shares on an SMB server, use the `net rpc share list` command. Optionally, pass the `-S server_name` parameter to the command to list the shares of a remote server. For example:

```
~\]# net rpc share list -U "DOMAIN\administrator" -S example
```

```
Enter DOMAIN\administrator's password:
IPC$
share_1
share_2
...
```

**NOTE**

Shares hosted on a Samba server that have `browseable = no` set in their section in the `/etc/samba/smb.conf` file are not displayed in the output.

**Adding a Share**

The `net rpc share add` command enables you to add a share to an SMB server.

For example, to add a share named `example` on a remote Windows server that shares the `C:\example\` directory:

```
~\]# net rpc share add example="C:\example" -U "DOMAIN\administrator" -S server
```

**NOTE**

You must omit the trailing backslash in the path when specifying a Windows directory name.

To use the command to add a share to a Samba server:

- The user specified in the `-U` parameter must have the `SeDiskOperatorPrivilege` privilege granted.
You must write a script that adds a share section to the `/etc/samba/smb.conf` file and reloads Samba. The script must be set in the `add share command` parameter in the `[global]` section in `/etc/samba/smb.conf`. For further details, see the `add share command` description in the `smb.conf(5)` man page.

Removing a Share

The `net rpc share delete` command enables you to remove a share from an SMB server.

For example, to remove the share named `example` from a remote Windows server:

```bash
~]# net rpc share delete example -U "DOMAIN\administrator" -S server
```

To use the command to remove a share from a Samba server:

- The user specified in the `-U` parameter must have the `SeDiskOperatorPrivilege` privilege granted.
- You must write a script that removes the share's section from the `/etc/samba/smb.conf` file and reloads Samba. The script must be set in the `delete share command` parameter in the `[global]` section in `/etc/samba/smb.conf`. For further details, see the `delete share command` description in the `smb.conf(5)` man page.

15.1.10.1.4. Using the `net user` Command

The `net user` command enables you to perform the following actions on an AD DC or NT4 PDC:

- List all user accounts
- Add users
- Remove Users

**NOTE**

Specifying a connection method, such as `ads` for AD domains or `rpc` for NT4 domains, is only required when you list domain user accounts. Other user-related subcommands can auto-detect the connection method.

Pass the `-U user_name` parameter to the command to specify a user that is allowed to perform the requested action.

Listing Domain User Accounts

To list all users in an AD domain:

```bash
~]# net ads user -U "DOMAIN\administrator"
```

To list all users in an NT4 domain:

```bash
~]# net rpc user -U "DOMAIN\administrator"
```

Adding a User Account to the Domain

On a Samba domain member, you can use the `net user add` command to add a user account to the domain.
For example, add the user account to the domain:

Procedure 15.22. Adding a User Account to the Domain

1. Add the account:

```
~]# net user add user password -U "DOMAIN\administrator"
User user added
```

2. Optionally, use the remote procedure call (RPC) shell to enable the account on the AD DC or NT4 PDC. For example:

```
~]# net rpc shell -U DOMAIn\administrator -S DC_or_PDC_name
Talking to domain DOMAIn (S-1-5-21-1424831554-512457234-5642315751)
net rpc> user edit disabled user no
Set user's disabled flag from [yes] to [no]
net rpc> exit
```

Deleting a User Account from the Domain

On a Samba domain member, you can use the `net user delete` command to remove a user account from the domain.

For example, to remove the user account from the domain:

```
~]# net user delete user -U "DOMAIN\administrator"
User user deleted
```

15.1.10.1.5. Using the `net usershare` Command

See Section 15.1.7.4, “Enabling Users to Share Directories on a Samba Server”.

15.1.10.2. Using the `rpcclient` Utility

The `rpcclient` utility enables you to manually execute client-side Microsoft Remote Procedure Call (MS-RPC) functions on a local or remote SMB server. However, most of the features are integrated into separate utilities provided by Samba. Use `rpcclient` only for testing MS-PRC functions.

For example, you can use the utility to:

- Manage the printer Spool Subsystem (SPOOLSS).

Example 15.9. Assigning a Driver to a Printer

```
~]# rpcclient server_name -U "DOMAIN\administrator" \
    -c 'setdriver "printer_name" "driver_name"'
Enter DOMAIN\Administrators password:
Successfully set printer_name to driver driver_name.
```

- Retrieve information about an SMB server.
Example 15.10. Listing all File Shares and Shared Printers

```bash
~]# rpcclient server_name -U "DOMAIN\administrator" -c 'netshareenum'
Enter DOMAIN\administrators password:
netname: Example_Share
remark:
path: C:srv\samba\example_share
password:
netname: Example_Printer
remark:
path: C:var\spool\samba
password:
```

- Perform actions using the Security Account Manager Remote (SAMR) protocol.

Example 15.11. Listing Users on an SMB Server

```bash
~]# rpcclient server_name -U "DOMAIN\administrator" -c 'enumdomusers'
Enter DOMAIN\administrators password:
user:[user1] rid:[0x3e8]
user:[user2] rid:[0x3e9]
```

If you run the command against a standalone server or a domain member, it lists the users in the local database. Running the command against an AD DC or NT4 PDC lists the domain users.

For a complete list of supported subcommands, see COMMANDS section in the rpcclient(1) man page.

15.10.3. Using the samba-regedit Application

Certain settings, such as printer configurations, are stored in the registry on the Samba server. You can use the ncurses-based samba-regedit application to edit the registry of a Samba server.
To start the application, enter:

```
~]# samba-regedit
```

Use the following keys:

- Cursor up and cursor down: Navigate through the registry tree and the values.
- **Enter**: Opens a key or edits a value.
- **Tab**: Switches between the Key and Value pane.
- **Ctrl+C**: Closes the application.

### 15.1.10.4. Using the `smbcacls` Utility

See Section 15.1.7.3, “Managing ACLs on an SMB Share Using `smbcacls`”.

### 15.1.10.5. Using the `smbclient` Utility

The `smbclient` utility enables you to access file shares on an SMB server, similarly to a command-line FTP client. You can use it, for example, to upload and download files to and from a share.

For example, to authenticate to the `example` share hosted on `server` using the `DOMAIN\user` account:

```
~]# smbclient -U "DOMAIN\user" //server/example
Enter domain\user's password:
smb: >
```

After `smbclient` connected successfully to the share, the utility enters the interactive mode and shows the following prompt:
To display all available commands in the interactive shell, enter:

```
smb: \> help
```

To display the help for a specific command, enter:

```
smb: \> help command_name
```

For further details and descriptions of the commands available in the interactive shell, see the `smbclient(1)` man page.

### 15.1.10.5.1. Using `smbclient` in Interactive Mode

If you use `smbclient` without the `-c` parameter, the utility enters the interactive mode.

The following procedure shows how to connect to an SMB share and download a file from a subdirectory:

**Procedure 15.23. Downloading a File from an SMB Share Using `smbclient`**

1. Connect to the share:
   ```
   ~\]# smbclient -U "DOMAIN\user_name" //server_name/share_name
   ```

2. Change into the `/example/` directory:
   ```
   smb: \> cd /example/
   ```

3. List the files in the directory:
   ```
   smb: \example\> ls
   .          D         0  Mon Sep 1 10:00:00 2017
   ..         D         0  Mon Sep 1 10:00:00 2017
   example.txt  N  1048576  Mon Sep 1 10:00:00 2017
   9950208 blocks of size 1024. 8247144 blocks available
   ```

4. Download the `example.txt` file:
   ```
   smb: \example\> get example.txt
   getting file \directory\subdirectory\example.txt of size 1048576 as example.txt (511975,0 KiloBytes/sec) (average 170666,7 KiloBytes/sec)
   ```

5. Disconnect from the share:
   ```
   smb: \example\> exit
   ```

### 15.1.10.5.2. Using `smbclient` in Scripting Mode
If you pass the `-c commands` parameter to `smbclient`, you can automatically execute the commands on the remote SMB share. This enables you to use `smbclient` in scripts.

The following command shows how to connect to an SMB share and download a file from a subdirectory:

```
~$# smbclient -U DOMAIN\user_name //server_name/share_name \
    -c "cd /example/ ; get example.txt ; exit"
```

### 15.1.10.6. Using the `smbcontrol` Utility

The `smbcontrol` utility enables you to send command messages to the `smbd`, `nmbd`, `winbindd`, or all of these services. These control messages instruct the service, for example, to reload its configuration.

**Example 15.12. Reloading the Configuration of the `smbd`, `nmbd`, and `winbindd` Service**

For example, to reload the configuration of the `smbd`, `nmbd`, `winbindd`, send the `reload-config` message-type to the `all` destination:

```
~$# smbcontrol all reload-config
```

For further details and a list of available command message types, see the `smbcontrol(1)` man page.

### 15.1.10.7. Using the `smbpasswd` Utility

The `smbpasswd` utility manages user accounts and passwords in the local Samba database.

If you run the command as a user, `smbpasswd` changes the Samba password of the user. For example:

```
[user@server ~]$ smbpasswd
New SMB password: 
Retype new SMB password: 
```

If you run `smbpasswd` as the `root` user, you can use the utility, for example, to:

- Create a new user:

```
[root@server ~]$ smbpasswd -a user_name
New SMB password: 
Retype new SMB password: 
Added user user_name.
```

**NOTE**

Before you can add a user to the Samba database, you must create the account in the local operating system. See Section 3.3.1, “Adding a New User”

- Enable a Samba user:
[root@server ~]# smbpasswd -e user_name
Enabled user user_name.

- Disable a Samba user:

[root@server ~]# smbpasswd -x user_name
Disabled user user_name.

- Delete a user:

[root@server ~]# smbpasswd -x user_name
Deleted user user_name.

For further details, see the smbpasswd(8) man page.

15.1.10.8. Using the smbstatus Utility

The smbstatus utility reports on:

- Connections per PID of each smbd daemon to the Samba server. This report includes the user name, primary group, SMB protocol version, encryption, and signing information.

- Connections per Samba share. This report includes the PID of the smbd daemon, the IP of the connecting machine, the time stamp when the connection was established, encryption, and signing information.

- A list of locked files. The report entries include further details, such as opportunistic lock (oplock) types

Example 15.13. Output of the smbstatus Utility

~]# smbstatus

Samba version 4.6.2
PID Username Group Machine
Protocol Version Encryption Signing
--------------------------------------------------------------------
--------------------------------------------------------------------
963  DOMAIN\administrator  DOMA IN\domain users  client-pc
(ipv4:192.0.2.1:57786)  SMB3_02 - AES-128-CMAC

Service  pid  Machine    Connected at                  Encryption
Signing:
--------------------------------------------------------------------
-------------------------
example  969  192.0.2.1  Mo Sep  1 10:00:00 2017 CEST  - AES-
128-CMAC

Locked files:
Pid Uid DenyMode Access R/W Oplock SharePath
Name    Time
--------------------------------------------------------------------
----------------------------------------
969  10000  DENY_WRITE 0x120089  RDONLY  LEASE(RWH)  /srv/samba/example
For further details, see the smbstatus(1) man page.

15.1.10.9. Using the smbtar Utility

The smbtar utility backs up the content of an SMB share or a subdirectory of it and stores the content in a tar archive. Alternatively, you can write the content to a tape device.

For example, to back up the content of the demo directory on the //server/example/ share and store the content in the /root/example.tar archive:

```
~]# smbtar -s server -x example -u user_name -p password -t /root/example.tar
```

For further details, see the smbtar(1) man page.

15.1.10.10. Using the testparm Utility

See Section 15.1.2, “Verifying the smb.conf File by Using the testparm Utility”.

15.1.10.11. Using the wbinfo Utility

The wbinfo utility queries and returns information created and used by the winbindd service.

**NOTE**

The winbindd service must be configured and running to use wbinfo.

You can use wbinfo, for example, to:

- List domain users:

  ```
  ~]# wbinfo -u
  AD\administrator
  AD\guest
  ...
  ```

- List domain groups:

  ```
  ~]# wbinfo -g
  AD\domain computers
  AD\domain admins
  AD\domain users
  ...
  ```

- Display the SID of a user:

  ```
  ~]# wbinfo --name-to-sid="AD\administrator"
  S-1-5-21-1762709870-351891212-3141221786-500 SID_USER (1)
  ```
Display information about domains and trusts:

```
~]# wbinfo --trusted-domains --verbose

<table>
<thead>
<tr>
<th>Domain Name</th>
<th>DNS Domain</th>
<th>Trust Type</th>
<th>Transitive</th>
<th>In</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUILTIN</td>
<td>None</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>server</td>
<td>None</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DOMAIN1</td>
<td>domain1.example.com</td>
<td>None</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DOMAIN2</td>
<td>domain2.example.com</td>
<td>External</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>
```

For further details, see the wbinfo(1) man page.

### 15.1.11. Additional Resources

- The Red Hat Samba packages include manual pages for all Samba commands and configuration files the package installs. For example, to display the man page of the `/etc/samba/smb.conf` file that explains all configuration parameters you can set in this file:

  ~]# man 5 smb.conf

- `/usr/share/docs/samba-version/`: Contains general documentation, example scripts, and LDAP schema files, provided by the Samba project.

- *Red Hat Cluster Storage Administration Guide* Provides information about setting up Samba and the Clustered Trivial Database (CDTB) to share directories stored on an GlusterFS volume.

- The *Clustered Samba Configuration* section in the *Red Hat Enterprise Linux 6 Cluster Administration Guide* describes how to set up a Samba high-availability installation. This documentation is currently not available for the latest Red Hat Enterprise Linux version.

### 15.2. FTP

The *File Transfer Protocol* (FTP) is one of the oldest and most commonly used protocols found on the Internet today. Its purpose is to reliably transfer files between computer hosts on a network without requiring the user to log directly in to the remote host or to have knowledge of how to use the remote system. It allows users to access files on remote systems using a standard set of simple commands.

This section outlines the basics of the FTP protocol and introduces *vsftpd*, which is the preferred FTP server in Red Hat Enterprise Linux.

#### 15.2.1. The File Transfer Protocol

FTP uses a client-server architecture to transfer files using the TCP network protocol. Because FTP is a rather old protocol, it uses unencrypted user name and password authentication. For this reason, it is considered an insecure protocol and should not be used unless absolutely necessary. However, because FTP is so prevalent on the Internet, it is often required for sharing files to the public. System administrators, therefore, should be aware of FTP's unique characteristics.

This section describes how to configure vsftpd to establish connections secured by TLS and how to
secure an FTP server with the help of SELinux. A good substitute for FTP is sftp from the OpenSSH suite of tools. For information about configuring OpenSSH and about the SSH protocol in general, refer to Chapter 11, OpenSSH.

Unlike most protocols used on the Internet, FTP requires multiple network ports to work properly. When an FTP client application initiates a connection to an FTP server, it opens port 21 on the server — known as the command port. This port is used to issue all commands to the server. Any data requested from the server is returned to the client via a data port. The port number for data connections, and the way in which data connections are initialized, vary depending upon whether the client requests the data in active or passive mode.

The following defines these modes:

active mode
Active mode is the original method used by the FTP protocol for transferring data to the client application. When an active-mode data transfer is initiated by the FTP client, the server opens a connection from port 20 on the server to the IP address and a random, unprivileged port (greater than 1024) specified by the client. This arrangement means that the client machine must be allowed to accept connections over any port above 1024. With the growth of insecure networks, such as the Internet, the use of firewalls for protecting client machines is now prevalent. Because these client-side firewalls often deny incoming connections from active-mode FTP servers, passive mode was devised.

passive mode
Passive mode, like active mode, is initiated by the FTP client application. When requesting data from the server, the FTP client indicates it wants to access the data in passive mode and the server provides the IP address and a random, unprivileged port (greater than 1024) on the server. The client then connects to that port on the server to download the requested information.

While passive mode does resolve issues for client-side firewall interference with data connections, it can complicate administration of the server-side firewall. You can reduce the number of open ports on a server by limiting the range of unprivileged ports on the FTP server. This also simplifies the process of configuring firewall rules for the server.

15.2.2. The vsftpd Server
The Very Secure FTP Daemon (vsftpd) is designed from the ground up to be fast, stable, and, most importantly, secure. vsftpd is the only stand-alone FTP server distributed with Red Hat Enterprise Linux, due to its ability to handle large numbers of connections efficiently and securely.

The security model used by vsftpd has three primary aspects:

- **Strong separation of privileged and non-privileged processes**— Separate processes handle different tasks, and each of these processes runs with the minimal privileges required for the task.

- **Tasks requiring elevated privileges are handled by processes with the minimal privilege necessary**— By taking advantage of compatibilities found in the libcap library, tasks that usually require full root privileges can be executed more safely from a less privileged process.

- **Most processes run in a chroot jail**— Whenever possible, processes are change-rooted to the directory being shared; this directory is then considered a chroot jail. For example, if the /var/ftp/ directory is the primary shared directory, vsftpd reassigns /var/ftp/ to the

280
new root directory, known as /. This disallows any potential malicious hacker activities for any directories not contained in the new root directory.

Use of these security practices has the following effect on how vsftpd deals with requests:

- **The parent process runs with the least privileges required**— The parent process dynamically calculates the level of privileges it requires to minimize the level of risk. Child processes handle direct interaction with the FTP clients and run with as close to no privileges as possible.

- **All operations requiring elevated privileges are handled by a small parent process**— Much like the Apache HTTP Server, vsftpd launches unprivileged child processes to handle incoming connections. This allows the privileged, parent process to be as small as possible and handle relatively few tasks.

- **All requests from unprivileged child processes are distrusted by the parent process**— Communication with child processes is received over a socket, and the validity of any information from child processes is checked before being acted on.

- **Most interactions with FTP clients are handled by unprivileged child processes in a chroot jail**— Because these child processes are unprivileged and only have access to the directory being shared, any crashed processes only allow the attacker access to the shared files.

### 15.2.2.1. Starting and Stopping vsftpd

To start the vsftpd service in the current session, type the following at a shell prompt as **root**:

```bash
~]$ systemctl start vsftpd.service
```

To stop the service in the current session, type as **root**:

```bash
~]$ systemctl stop vsftpd.service
```

To restart the vsftpd service, run the following command as **root**:

```bash
~]$ systemctl restart vsftpd.service
```

This command stops and immediately starts the vsftpd service, which is the most efficient way to make configuration changes take effect after editing the configuration file for this FTP server. Alternatively, you can use the following command to restart the vsftpd service only if it is already running:

```bash
~]$ systemctl try-restart vsftpd.service
```

By default, the vsftpd service does **not** start automatically at boot time. To configure the vsftpd service to start at boot time, type the following at a shell prompt as **root**:

```bash
~]$ systemctl enable vsftpd.service
```

Created symlink from /etc/systemd/system/multi-user.target.wants/vsftpd.service to /usr/lib/systemd/system/vsftpd.service.

For more information on how to manage system services in Red Hat Enterprise Linux 7, see Chapter 9, *Managing Services with systemd*. 

281
15.2.2.2. Starting Multiple Copies of vsftpd

Sometimes, one computer is used to serve multiple FTP domains. This is a technique called multihoming. One way to multihome using vsftpd is by running multiple copies of the daemon, each with its own configuration file.

To do this, first assign all relevant IP addresses to network devices or alias network devices on the system. For more information about configuring network devices, device aliases, and additional information about network configuration scripts, see the Red Hat Enterprise Linux 7 Networking Guide.

Next, the DNS server for the FTP domains must be configured to reference the correct machine. For information about BIND, the DNS protocol implementation used in Red Hat Enterprise Linux, and its configuration files, see the Red Hat Enterprise Linux 7 Networking Guide.

For vsftpd to answer requests on different IP addresses, multiple copies of the daemon must be running. To facilitate launching multiple instances of the vsftpd daemon, a special systemd service unit (vsftpd@.service) for launching vsftpd as an instantiated service is supplied in the vsftpd package.

In order to make use of this service unit, a separate vsftpd configuration file for each required instance of the FTP server must be created and placed in the /etc/vsftpd/ directory. Note that each of these configuration files must have a unique name (such as /etc/vsftpd/vsftpd-site-2.conf) and must be readable and writable only by the root user.

Within each configuration file for each FTP server listening on an IPv4 network, the following directive must be unique:

```
listen_address=N.N.N.N
```

Replace N.N.N.N with a unique IP address for the FTP site being served. If the site is using IPv6, use the listen_address6 directive instead.

Once there are multiple configuration files present in the /etc/vsftpd/ directory, individual instances of the vsftpd daemon can be started by executing the following command as root:

```
~# systemctl start vsftpd@configuration-file-name.service
```

In the above command, replace configuration-file-name with the unique name of the requested server's configuration file, such as vsftpd-site-2. Note that the configuration file's .conf extension should not be included in the command.

If you want to start several instances of the vsftpd daemon at once, you can make use of a systemd target unit file (vsftpd.target), which is supplied in the vsftpd package. This systemd target causes an independent vsftpd daemon to be launched for each available vsftpd configuration file in the /etc/vsftpd/ directory. Execute the following command as root to enable the target:

```
~# systemctl enable vsftpd.target
Created symlink from /etc/systemd/system/multi-user.target.wants/vsftpd.target to /usr/lib/systemd/system/vsftpd.target.
```

The above command configures the systemd service manager to launch the vsftpd service (along with the configured vsftpd server instances) at boot time. To start the service immediately, without rebooting the system, execute the following command as root:
 systemct1 start vsftpd.target

See Section 9.3, “Working with systemd Targets” for more information on how to use systemd targets to manage services.

Other directives to consider altering on a per-server basis are:

- anon_root
- local_root
- vsftpd_log_file
- xferlog_file

15.2.2.3. Encrypting vsftpd Connections Using TLS

In order to counter the inherently insecure nature of FTP, which transmits user names, passwords, and data without encryption by default, the vsftpd daemon can be configured to utilize the TLS protocol to authenticate connections and encrypt all transfers. Note that an FTP client that supports TLS is needed to communicate with vsftpd with TLS enabled.

**NOTE**

SSL (Secure Sockets Layer) is the name of an older implementation of the security protocol. The new versions are called TLS (Transport Layer Security). Only the newer versions (TLS) should be used as SSL suffers from serious security vulnerabilities. The documentation included with the vsftpd server, as well as the configuration directives used in the vsftpd.conf file, use the SSL name when referring to security-related matters, but TLS is supported and used by default when the ssl_enable directive is set to YES.

Set the ssl_enable configuration directive in the vsftpd.conf file to YES to turn on TLS support. The default settings of other TLS-related directives that become automatically active when the ssl_enable option is enabled provide for a reasonably well-configured TLS set up. This includes, among other things, the requirement to only use the TLS v1 protocol for all connections (the use of the insecure SSL protocol versions is disabled by default) or forcing all non-anonymous logins to use TLS for sending passwords and data transfers.

**Example 15.14. Configuring vsftpd to Use TLS**

In this example, the configuration directives explicitly disable the older SSL versions of the security protocol in the vsftpd.conf file:

```
ssl_enable=YES
ssl_tlsv1=YES
ssl_sslv2=NO
ssl_sslv3=NO
```

Restart the vsftpd service after you modify its configuration:

```~## systemct1 restart vsftpd.service```
See the vsftpd.conf(5) manual page for other TLS-related configuration directives for fine-tuning the use of TLS by vsftpd.

15.2.2.4. SELinux Policy for vsftpd

The SELinux policy governing the vsftpd daemon (as well as other ftplib processes), defines a mandatory access control, which, by default, is based on least access required. In order to allow the FTP daemon to access specific files or directories, appropriate labels need to be assigned to them.

For example, in order to be able to share files anonymously, the public_content_t label must be assigned to the files and directories to be shared. You can do this using the chcon command as root:

```bash
~# chcon -R -t public_content_t /path/to/directory
```

In the above command, replace /path/to/directory with the path to the directory to which you want to assign the label. Similarly, if you want to set up a directory for uploading files, you need to assign that particular directory the public_content_rwlock_t label. In addition to that, the allow_ftpd_anon_write SELinux Boolean option must be set to 1. Use the setsebool command as root to do that:

```bash
~# setsebool -P allow_ftpd_anon_write=1
```

If you want local users to be able to access their home directories through FTP, which is the default setting on Red Hat Enterprise Linux 7, the ftp_home_dir Boolean option needs to be set to 1. If vsftpd is to be allowed to run in standalone mode, which is also enabled by default on Red Hat Enterprise Linux 7, the ftplib_is_daemon option needs to be set to 1 as well.

See the ftpd_selinux(8) manual page for more information, including examples of other useful labels and Boolean options, on how to configure the SELinux policy pertaining to FTP. Also, see the Red Hat Enterprise Linux 7 SELinux User’s and Administrator’s Guide for more detailed information about SELinux in general.

15.2.3. Additional Resources

For more information about vsftpd, see the following resources.

15.2.3.1. Installed Documentation

- The /usr/share/doc/vsftpd-version-number/ directory — Replace version-number with the installed version of the vsftpd package. This directory contains a README file with basic information about the software. The TUNING file contains basic performance-tuning tips and the SECURITY/ directory contains information about the security model employed by vsftpd.

- vsftpd-related manual pages — There are a number of manual pages for the daemon and the configuration files. The following lists some of the more important manual pages.

  Server Applications
  
  o vsftpd(8) — Describes available command-line options for vsftpd.

  Configuration Files
  
  o vsftpd.conf(5) — Contains a detailed list of options available within the configuration file.
vsftpd.conf — Contains a detailed list of options available within the configuration file for vsftpd.

hosts_access(5) — Describes the format and options available within the TCP wrappers configuration files: hosts.allow and hosts.deny.

Interaction with SELinux

ftpd_selinux(8) — Contains a description of the SELinux policy governing ftpd processes as well as an explanation of the way SELinux labels need to be assigned and Booleans set.

15.2.3.2. Online Documentation

About vsftpd and FTP in General

- [http://vsftpd.beasts.org/](http://vsftpd.beasts.org/) — The vsftpd project page is a great place to locate the latest documentation and to contact the author of the software.

- [http://slacksite.com/other/ftp.html](http://slacksite.com/other/ftp.html) — This website provides a concise explanation of the differences between active and passive-mode FTP.

Red Hat Enterprise Linux Documentation

- [Red Hat Enterprise Linux 7 Networking Guide](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/networking_guide/) — The Networking Guide for Red Hat Enterprise Linux 7 documents relevant information regarding the configuration and administration of network interfaces, networks, and network services in this system. It provides an introduction to the hostnamectl utility and explains how to use it to view and set host names on the command line, both locally and remotely.

- [Red Hat Enterprise Linux 7 SELinux User’s and Administrator’s Guide](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/selinux_user_and_administrator_guides/) — The SELinux User’s and Administrator’s Guide for Red Hat Enterprise Linux 7 describes the basic principles of SELinux and documents in detail how to configure and use SELinux with various services such as the Apache HTTP Server, Postfix, PostgreSQL, or OpenShift. It explains how to configure SELinux access permissions for system services managed by systemd.

Relevant RFC Documents

- [RFC 0959](https://tools.ietf.org/html/rfc0959) — The original Request for Comments (RFC) of the FTP protocol from the IETF.

- [RFC 2228](https://tools.ietf.org/html/rfc2228) — FTP security extensions. vsftpd implements the small subset needed to support TLS and SSL connections.

15.3. PRINT SETTINGS

The Print Settings tool serves for printer configuring, maintenance of printer configuration files, print spool directories and print filters, and printer classes management.

The tool is based on the Common Unix Printing System (CUPS). If you upgraded the system from a previous Red Hat Enterprise Linux version that used CUPS, the upgrade process preserved the configured printers.

**IMPORTANT**

The `cupsd.conf` man page documents configuration of a CUPS server. It includes directives for enabling SSL support. However, CUPS does not allow control of the protocol versions used. Due to the vulnerability described in Resolution for POODLE SSLv3.0 vulnerability (CVE-2014-3566) for components that do not allow SSLv3 to be disabled via configuration settings, Red Hat recommends that you do not rely on this for security. It is recommend that you use stunnel to provide a secure tunnel and disable SSLv3. For more information on using stunnel, see the Red Hat Enterprise Linux 7 Security Guide.

For ad-hoc secure connections to a remote system's Print Settings tool, use X11 forwarding over SSH as described in Section 11.4.1, “X11 Forwarding”.

**NOTE**

You can perform the same and additional operations on printers directly from the CUPS web application or command line. To access the application, in a web browser, go to `http://localhost:631/`. For CUPS manuals refer to the links on the Home tab of the web site.

15.3.1. Starting the Print Settings Configuration Tool

With the Print Settings configuration tool you can perform various operations on existing printers and set up new printers. You can also use CUPS directly (go to `http://localhost:631/` to access the CUPS web application).

To start the Print Settings tool from the command line, type `system-config-printer` at a shell prompt. The Print Settings tool appears. Alternatively, if using the GNOME desktop, press the Super key to enter the Activities Overview, type Print Settings and then press Enter. The Print Settings tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Spacebar.

The Print Settings window depicted in Figure 15.1, “Print Settings window” appears.
15.3.2. Starting Printer Setup

Printer setup process varies depending on the printer queue type.

If you are setting up a local printer connected with USB, the printer is discovered and added automatically. You will be prompted to confirm the packages to be installed and provide an administrator or the root user password. Local printers connected with other port types and network printers need to be set up manually.

Follow this procedure to start a manual printer setup:

1. Start the Print Settings tool (refer to Section 15.3.1, “Starting the Print Settings Configuration Tool”).

2. Go to Server → New → Printer.

3. In the Authenticate dialog box, enter an administrator or root user password. If this is the first time you have configured a remote printer you will be prompted to authorize an adjustment to the firewall.

4. Select the printer connection type and provide its details in the area on the right.

15.3.3. Adding a Local Printer

Follow this procedure to add a local printer connected with other than a serial port:

1. Open the Add printer dialog (refer to Section 15.3.2, “Starting Printer Setup”).

2. If the device does not appear automatically, select the port to which the printer is connected in the list on the left (such as Serial Port #1 or LPT #1).

3. On the right, enter the connection properties:

   for Other
URI (for example file:/dev/lp0)

for Serial Port
Baud Rate
Parity
Data Bits
Flow Control

Figure 15.2. Adding a local printer

4. Click Forward.

5. Select the printer model. See Section 15.3.8, “Selecting the Printer Model and Finishing” for details.

15.3.4. Adding an AppSocket/HP JetDirect printer

Follow this procedure to add an AppSocket/HP JetDirect printer:

1. Open the New Printer dialog (refer to Section 15.3.1, “Starting the Print Settings Configuration Tool”).
2. In the list on the left, select Network Printer → AppSocket/HP JetDirect.

3. On the right, enter the connection settings:

   **Hostname**
   Printer host name or IP address.

   **Port Number**
   Printer port listening for print jobs (9100 by default).

   ![Select Device](image)

   **Location of the network printer**
   - Host: lenore.example.com
   - Port number: 9100

   Figure 15.3. Adding a JetDirect printer

4. Click Forward.

5. Select the printer model. See Section 15.3.8, “Selecting the Printer Model and Finishing” for details.

### 15.3.5. Adding an IPP Printer

An IPP printer is a printer attached to a different system on the same TCP/IP network. The system this printer is attached to may either be running CUPS or simply configured to use IPP.

If a firewall is enabled on the printer server, then the firewall must be configured to allow incoming TCP connections on port 631. Note that the CUPS browsing protocol allows client machines to discover
shared CUPS queues automatically. To enable this, the firewall on the client machine must be configured to allow incoming UDP packets on port 631.

Follow this procedure to add an IPP printer:

1. Open the New Printer dialog (refer to Section 15.3.2, “Starting Printer Setup”).

2. In the list of devices on the left, select Network Printer and Internet Printing Protocol (ipp) or Internet Printing Protocol (https).

3. On the right, enter the connection settings:
   
   **Host**
   
   The host name of the IPP printer.
   
   **Queue**
   
   The queue name to be given to the new queue (if the box is left empty, a name based on the device node will be used).

4. Click Forward to continue.

5. Select the printer model. See Section 15.3.8, “Selecting the Printer Model and Finishing” for details.

15.3.6. Adding an LPD/LPR Host or Printer
Follow this procedure to add an LPD/LPR host or printer:

1. Open the New Printer dialog (refer to Section 15.3.2, “Starting Printer Setup”).

2. In the list of devices on the left, select Network Printer → LPD/LPR Host or Printer.

3. On the right, enter the connection settings:

   **Host**
   
   The host name of the LPD/LPR printer or host.

   Optionally, click **Probe** to find queues on the LPD host.

   **Queue**
   
   The queue name to be given to the new queue (if the box is left empty, a name based on the device node will be used).

4. Click **Forward** to continue.

5. Select the printer model. See Section 15.3.8, “Selecting the Printer Model and Finishing” for details.

**15.3.7. Adding a Samba (SMB) printer**

Follow this procedure to add a Samba printer:
NOTE

Note that in order to add a Samba printer, you need to have the samba-client package installed. You can do so by running, as root:

```
yum install samba-client
```

For more information on installing packages with Yum, refer to Section 8.2.4, “Installing Packages”.

1. Open the New Printer dialog (refer to Section 15.3.2, “Starting Printer Setup”).

2. In the list on the left, select Network Printer → Windows Printer via SAMBA.

3. Enter the SMB address in the smb:// field. Use the format `computer name/printer share` In Figure 15.6, “Adding a SMB printer”, the `computer name` is `dellbox` and the `printer share` is `r2`.

4. Click Browse to see the available workgroups/domains. To display only queues of a particular host, type in the host name (NetBios name) and click Browse.

5. Select either of the options:
   - Prompt user if authentication is required: user name and password are collected from the user when printing a document.
   - Set authentication details now: provide authentication information now so it is...
not required later. In the **Username** field, enter the user name to access the printer. This user must exist on the SMB system, and the user must have permission to access the printer. The default user name is typically **guest** for Windows servers, or **nobody** for Samba servers.

6. Enter the **Password** (if required) for the user specified in the **Username** field.

**WARNING**

Samba printer user names and passwords are stored in the printer server as unencrypted files readable by **root** and the Linux Printing Daemon, **lpd**. Thus, other users that have **root** access to the printer server can view the user name and password you use to access the Samba printer.

Therefore, when you choose a user name and password to access a Samba printer, it is advisable that you choose a password that is different from what you use to access your local Red Hat Enterprise Linux system.

If there are files shared on the Samba print server, it is recommended that they also use a password different from what is used by the print queue.

7. Click **Verify** to test the connection. Upon successful verification, a dialog box appears confirming printer share accessibility.

8. Click **Forward**.

9. Select the printer model. See Section 15.3.8, “Selecting the Printer Model and Finishing” for details.

**15.3.8. Selecting the Printer Model and Finishing**

Once you have properly selected a printer connection type, the system attempts to acquire a driver. If the process fails, you can locate or search for the driver resources manually.

Follow this procedure to provide the printer driver and finish the installation:

1. In the window displayed after the automatic driver detection has failed, select one of the following options:

   - **Select a Printer from database** — the system chooses a driver based on the selected make of your printer from the list of **Makes**. If your printer model is not listed, choose **Generic**.

   - **Provide PPD file** — the system uses the provided **PostScript Printer Description** (PPD) file for installation. A PPD file may also be delivered with your printer as being normally provided by the manufacturer. If the PPD file is available, you can choose this option and use the browser bar below the option description to select the PPD file.
Search for a printer driver to download—enter the make and model of your printer into the Make and model field to search on OpenPrinting.org for the appropriate packages.

Choose Driver

- Select printer from database
- Provide PPD file
- Search for a printer driver to download

The foomatic printer database contains various manufacturer provided PostScript Printer Description (PPD) files and also can generate PPD files for a large number of (non PostScript) printers. But in general manufacturer provided PPD files provide better access to the specific features of the printer.

![Figure 15.7. Selecting a printer brand](image)

2. Depending on your previous choice provide details in the area displayed below:
   - Printer brand for the Select printer from database option.
   - PPD file location for the Provide PPD file option.
   - Printer make and model for the Search for a printer driver to download option.

3. Click Forward to continue.

4. If applicable for your option, window shown in Figure 15.8, “Selecting a printer model” appears. Choose the corresponding model in the Models column on the left.

**NOTE**

On the right, the recommended printer driver is automatically selected; however, you can select another available driver. The print driver processes the data that you want to print into a format the printer can understand. Since a local printer is attached directly to your computer, you need a printer driver to process the data that is sent to the printer.
5. **Click Forward.**

6. **Under the Describe Printer enter a unique name for the printer in the Printer Name field.** The printer name can contain letters, numbers, dashes (-), and underscores (_); it **must not** contain any spaces. You can also use the Description and Location fields to add further printer information. Both fields are optional, and may contain spaces.
Figure 15.9. Printer setup

7. Click Apply to confirm your printer configuration and add the print queue if the settings are correct. Click Back to modify the printer configuration.

8. After the changes are applied, a dialog box appears allowing you to print a test page. Click Yes to print a test page now. Alternatively, you can print a test page later as described in Section 15.3.9, “Printing a Test Page”.

15.3.9. Printing a Test Page

After you have set up a printer or changed a printer configuration, print a test page to make sure the printer is functioning properly:

1. Right-click the printer in the Printing window and click Properties.

2. In the Properties window, click Settings on the left.

3. On the displayed Settings tab, click the Print Test Page button.

15.3.10. Modifying Existing Printers

To delete an existing printer, in the Print Settings window, select the printer and go to Printer → Delete. Confirm the printer deletion. Alternatively, press the Delete key.

To set the default printer, right-click the printer in the printer list and click the Set as Default button in the context menu.
15.3.10.1. The Settings Page

To change printer driver configuration, double-click the corresponding name in the Printer list and click the Settings label on the left to display the Settings page.

You can modify printer settings such as make and model, print a test page, change the device location (URI), and more.

![Settings page](image)

**Figure 15.10. Settings page**

15.3.10.2. The Policies Page

Click the Policies button on the left to change settings in printer state and print output.

You can select the printer states, configure the Error Policy of the printer (you can decide to abort the print job, retry, or stop it if an error occurs).

You can also create a banner page (a page that describes aspects of the print job such as the originating printer, the user name from which the job originated, and the security status of the document being printed): click the Starting Banner or Ending Banner drop-down menu and choose the option that best describes the nature of the print jobs (for example, confidential).

15.3.10.2.1. Sharing Printers

On the Policies page, you can mark a printer as shared: if a printer is shared, users published on the network can use it. To allow the sharing function for printers, go to Server → Settings and select Publish shared printers connected to this system.
Make sure that the firewall allows incoming TCP connections to port 631, the port for the Network Printing Server (IPP) protocol. To allow IPP traffic through the firewall on Red Hat Enterprise Linux 7, make use of `firewalld`'s IPP service. To do so, proceed as follows:

**Procedure 15.24. Enabling IPP Service in `firewalld`**

1. To start the graphical `firewall-config` tool, press the Super key to enter the Activities Overview, type `firewall` and then press Enter. The Firewall Configuration window opens. You will be prompted for an administrator or root password.

   Alternatively, to start the graphical firewall configuration tool using the command line, enter the following command as root user:

   ```bash
   ~]# firewall-config
   ```

   The Firewall Configuration window opens.

   Look for the word “Connected” in the lower left corner. This indicates that the `firewall-config` tool is connected to the user space daemon, `firewalld`.

   To immediately change the current firewall settings, ensure the drop-down selection menu labeled Configuration is set to Runtime. Alternatively, to edit the settings to be applied at the next system start, or firewall reload, select Permanent from the drop-down list.

2. Select the Zones tab and then select the firewall zone to correspond with the network interface to be used. The default is the public zone. The Interfaces tab shows what interfaces have been assigned to a zone.

3. Select the Services tab and then select the `ipp` service to enable sharing. The `ipp-client` service is required for accessing network printers.
4. Close the firewall-config tool.

For more information on opening and closing ports in firewalld, see the Red Hat Enterprise Linux 7 Security Guide.

15.3.10.2.2. The Access Control Page

You can change user-level access to the configured printer on the Access Control page. Click the Access Control label on the left to display the page. Select either Allow printing for everyone except these users or Deny printing for everyone except these users and define the user set below: enter the user name in the text box and click the Add button to add the user to the user set.

![Access Control page](image)

Figure 15.12. Access Control page

15.3.10.2.3. The Printer Options Page

The Printer Options page contains various configuration options for the printer media and output, and its content may vary from printer to printer. It contains general printing, paper, quality, and printing size settings.
15.3.10.2.4. Job Options Page

On the Job Options page, you can detail the printer job options. Click the Job Options label on the left to display the page. Edit the default settings to apply custom job options, such as number of copies, orientation, pages per side, scaling (increase or decrease the size of the printable area, which can be used to fit an oversize print area onto a smaller physical sheet of print medium), detailed text options, and custom job options.
Specify the default job options for this printer. Jobs arriving at this print server will have these options added if they are not already set by the application.

**Common Options**

- **Copies:** 1
- **Orientation:** Automatic rotation
- **Scale to fit:**
- **Pages per side:** 1
- **More**

**Image Options**

- **Mirror:**
- **Scaling:** 100%
- **More**

**Text Options**

- **Characters per inch:** 10.00
- **Lines per inch:** 6.00

**Figure 15.14. Job Options page**

15.3.10.2.5. Ink/Toner Levels Page

The Ink/Toner Levels page contains details on toner status if available and printer status messages. Click the Ink/Toner Levels label on the left to display the page.
15.3.10.3. Managing Print Jobs

When you send a print job to the printer daemon, such as printing a text file from Emacs or printing an image from GIMP, the print job is added to the print spool queue. The print spool queue is a list of print jobs that have been sent to the printer and information about each print request, such as the status of the request, the job number, and more.

During the printing process, the Printer Status icon appears in the Notification Area on the panel. To check the status of a print job, click the Printer Status, which displays a window similar to Figure 15.16, “GNOME Print Status”.

To cancel, hold, release, reprint or authenticate a print job, select the job in the GNOME Print Status and on the Job menu, click the respective command.

To view the list of print jobs in the print spool from a shell prompt, type the command `lpstat -o`. The last few lines look similar to the following:
Example 15.15. Example of \texttt{lpstat} -o output

```
$ lpstat -o
Charlie-60              twaugh            1024   Tue 08 Feb 2011 16:42:11 GMT
Aaron-61                twaugh            1024   Tue 08 Feb 2011 16:42:44 GMT
Ben-62                  root              1024   Tue 08 Feb 2011 16:45:42 GMT
```

If you want to cancel a print job, find the job number of the request with the command \texttt{lpstat -o} and then use the command \texttt{cancel job number}. For example, \texttt{cancel 60} would cancel the print job in Example 15.15, “Example of \texttt{lpstat} -o output”. You cannot cancel print jobs that were started by other users with the \texttt{cancel} command. However, you can enforce deletion of such job by issuing the \texttt{cancel -U root job_number} command. To prevent such canceling, change the printer operation policy to \texttt{Authenticated} to force \texttt{root} authentication.

You can also print a file directly from a shell prompt. For example, the command \texttt{lp sample.txt} prints the text file \texttt{sample.txt}. The print filter determines what type of file it is and converts it into a format the printer can understand.

15.3.11. Additional Resources

To learn more about printing on Red Hat Enterprise Linux, see the following resources.

**Installed Documentation**

- \texttt{lp(1)} – The manual page for the \texttt{lp} command that allows you to print files from the command line.
- \texttt{lpr(1)} – The manual page for the \texttt{lpr} command that allows you to print files from the command line.
- \texttt{cancel(1)} – The manual page for the command-line utility to remove print jobs from the print queue.
- \texttt{mpage(1)} – The manual page for the command-line utility to print multiple pages on one sheet of paper.
- \texttt{cupsd(8)} – The manual page for the CUPS printer daemon.
- \texttt{cupsd.conf(5)} – The manual page for the CUPS printer daemon configuration file.
- \texttt{classes.conf(5)} – The manual page for the class configuration file for CUPS.
- \texttt{lpstat(1)} – The manual page for the \texttt{lpstat} command, which displays status information about classes, jobs, and printers.

**Online Documentation**

- \texttt{http://www.linuxprinting.org/} – The OpenPrinting group on the Linux Foundation website contains a large amount of information about printing in Linux.
- \texttt{http://www.cups.org/} – The CUPS website provides documentation, FAQs, and newsgroups.

CHAPTER 16. CONFIGURING NTP USING THE CHRONY SUITE

Accurate time keeping is important for a number of reasons in IT. In networking for example, accurate time stamps in packets and logs are required. In Linux systems, the NTP protocol is implemented by a daemon running in user space.

The user space daemon updates the system clock running in the kernel. The system clock can keep time by using various clock sources. Usually, the Time Stamp Counter (TSC) is used. The TSC is a CPU register which counts the number of cycles since it was last reset. It is very fast, has a high resolution, and there are no interruptions.

There is a choice between the daemons ntpd and chronyd, available from the repositories in the ntp and chrony packages respectively.

This chapter describes the use of the chrony suite.

16.1. INTRODUCTION TO THE CHRONY SUITE

Chrony is an implementation of the Network Time Protocol (NTP). You can use Chrony:

- to synchronize the system clock with NTP servers,
- to synchronize the system clock with a reference clock, for example a GPS receiver,
- to synchronize the system clock with a manual time input,
- as an NTPv4 (RFC 5905) server or peer to provide a time service to other computers in the network.

Chrony performs well in a wide range of conditions, including intermittent network connections, heavily congested networks, changing temperatures (ordinary computer clocks are sensitive to temperature), and systems that do not run continuously, or run on a virtual machine.

Typical accuracy between two machines synchronized over the Internet is within a few milliseconds, and for machines on a LAN within tens of microseconds. Hardware timestamping or a hardware reference clock may improve accuracy between two machines synchronized to a sub-microsecond level.

Chrony consists of chronyd, a daemon that runs in user space, and chronyc, a command line program which can be used to monitor the performance of chronyd and to change various operating parameters when it is running.

16.1.1. Differences Between ntpd and chronyd

Things chronyd can do better than ntpd:

- chronyd can work well in an environment where access to the time reference is intermittent, whereas ntpd needs regular polling of time reference to work well.
- chronyd can perform well even when the network is congested for longer periods of time.
- chronyd can usually synchronize the clock faster and with better accuracy.
- **chronyd** quickly adapts to sudden changes in the rate of the clock, for example, due to changes in the temperature of the crystal oscillator, whereas **ntpd** may need a long time to settle down again.

- In the default configuration, **chronyd** never steps the time after the clock has been synchronized at system start, in order not to upset other running programs. **ntpd** can be configured to never step the time too, but it has to use a different means of adjusting the clock, which has some disadvantages including negative effect on accuracy of the clock.

- **chronyd** can adjust the rate of the clock on a Linux system in a larger range, which allows it to operate even on machines with a broken or unstable clock. For example, on some virtual machines.

- **chronyd** is smaller, it uses less memory and it wakes up the CPU only when necessary, which is better for power saving.

**Things chronyd can do that ntpd cannot do:**

- **chronyd** provides support for isolated networks where the only method of time correction is manual entry. For example, by the administrator looking at a clock. **chronyd** can examine the errors corrected at different updates to estimate the rate at which the computer gains or loses time, and use this estimate to adjust the computer clock subsequently.

- **chronyd** provides support to work out the rate of gain or loss of the real-time clock, for example the clock that maintains the time when the computer is turned off. It can use this data when the system boots to set the system time using an adapted value of time taken from the real-time clock. These real-time clock facilities are currently only available on Linux systems.

- **chronyd** supports hardware timestamping on Linux, which allows extremely accurate synchronization on local networks.

**Things ntpd can do that chronyd cannot do:**

- **ntpd** supports all operating modes from NTP version 4 (RFC 5905), including broadcast, multicast and manycast clients and servers. Note that the broadcast and multicast modes are, even with authentication, inherently less accurate and less secure than the ordinary server and client mode, and should generally be avoided.

- **ntpd** supports the Autokey protocol (RFC 5906) to authenticate servers with public-key cryptography. Note that the protocol has proven to be insecure and will be probably replaced with an implementation of the Network Time Security (NTS) specification.

- **ntpd** includes drivers for many reference clocks, whereas **chronyd** relies on other programs, for example **gpsd**, to access the data from the reference clocks using shared memory (SHM) or Unix domain socket (SOCK).

### 16.1.2. Choosing Between NTP Daemons

**Chrony** should be preferred for all systems except for the systems that are managed or monitored by tools that do not support chrony, or the systems that have a hardware reference clock which cannot be used with chrony.
NOTE

Systems which are required to perform authentication of packets with the Autokey protocol, can only be used with ntpd, because chronyd does not support this protocol. The Autokey protocol has serious security issues, and thus using this protocol should be avoided. Instead of Autokey, use authentication with symmetric keys, which is supported by both chronyd and ntpd. Chrony supports stronger hash functions like SHA256 and SHA512, while ntpd can use only MD5 and SHA1.

16.2. UNDERSTANDING CHRONY AND ITS CONFIGURATION

16.2.1. Understanding chronyd

The chrony daemon, chronyd, can be monitored and controlled by the command line utility chronyc. This utility provides a command prompt which allows entering a number of commands to query the current state of chronyd and make changes to its configuration. By default, chronyd accepts only commands from a local instance of chronyc, but it can be configured to accept monitoring commands also from remote hosts. The remote access should be restricted.

16.2.2. Understanding chronyc

The chrony daemon, chronyd, can be controlled by the command line utility chronyc. This utility provides a command prompt which allows entering a number of commands to query the current state of chronyd and to make changes to its configuration. The default configuration is for chronyd to only accept commands from a local instance of chronyc, but it can be configured to accept monitoring commands also from remote hosts. The remote access should be restricted.

16.2.3. Understanding the chrony Configuration Commands

The default configuration file for chronyd is /etc/chrony.conf. The -f option can be used to specify an alternate configuration file path. See the chronyd man page for further options. For a complete list of the directives that can be used see http://chrony.tuxfamily.org/manual.html#Configuration-file.

Below is a selection of chronyd configuration options:

Comments

Comments should be preceded by #, %, ; or !

allow

Optionally specify a host, subnet, or network from which to allow NTP connections to a machine acting as NTP server. The default is not to allow connections.

Examples:

1. allow 192.0.2.0/24

   Use this command to grant access to a specific network.

2. allow 2001:0db8:85a3::8a2e:0370:7334
Use this command to grant access to an IPv6.

The UDP port number 123 needs to be open in the firewall in order to allow the client access:

```
~# firewall-cmd --zone=public --add-port=123/udp
```

If you want to open port 123 permanently, use the `--permanent` option:

```
~# firewall-cmd --permanent --zone=public --add-port=123/udp
```

cmdallow

This is similar to the `allow` directive (see section `allow`), except that it allows control access (rather than NTP client access) to a particular subnet or host. (By “control access” is meant that `chronyc` can be run on those hosts and successfully connect to `chronyd` on this computer.) The syntax is identical. There is also a `cmddeny all` directive with similar behavior to the `cmdallow all` directive.

dumpdir

Path to the directory to save the measurement history across restarts of `chronyd` (assuming no changes are made to the system clock behavior whilst it is not running). If this capability is to be used (via the `dumponexit` command in the configuration file, or the `dump` command in `chronyc`), the `dumpdir` command should be used to define the directory where the measurement histories are saved.

dumponexit

If this command is present, it indicates that `chronyd` should save the measurement history for each of its time sources recorded whenever the program exits. (See the `dumpdir` command above).

hwtimestamp

The `hwtimestamp` directive enables hardware timestamping for extremely accurate synchronization. For more details, see `chrony.conf(5)` manual page.

local

The `local` keyword is used to allow `chronyd` to appear synchronized to real time from the viewpoint of clients polling it, even if it has no current synchronization source. This option is normally used on the “master” computer in an isolated network, where several computers are required to synchronize to one another, and the “master” is kept in line with real time by manual input.

An example of the command is:

```
local stratum 10
```

A large value of 10 indicates that the clock is so many hops away from a reference clock that its time is unreliable. If the computer ever has access to another computer which is ultimately synchronized to a reference clock, it will almost certainly be at a stratum less than 10. Therefore, the choice of a high value like 10 for the `local` command prevents the machine’s own time from ever being confused with real time, were it ever to leak out to clients that have visibility of real servers.
The **log** command indicates that certain information is to be logged. It accepts the following options:

**measurements**
This option logs the raw NTP measurements and related information to a file called `measurements.log`.

**statistics**
This option logs information about the regression processing to a file called `statistics.log`.

**tracking**
This option logs changes to the estimate of the system's gain or loss rate, and any slews made, to a file called `tracking.log`.

**rtc**
This option logs information about the system's real-time clock.

**refclocks**
This option logs the raw and filtered reference clock measurements to a file called `refclocks.log`.

**tempcomp**
This option logs the temperature measurements and system rate compensations to a file called `tempcomp.log`.

The log files are written to the directory specified by the **logdir** command. An example of the command is:

```
log measurements statistics tracking
```

**logdir**
This directive allows the directory where log files are written to be specified. An example of the use of this directive is:

```
logdir /var/log/chrony
```

**makestep**
Normally **chronyd** will cause the system to gradually correct any time offset, by slowing down or speeding up the clock as required. In certain situations, the system clock may be so far adrift that this slewing process would take a very long time to correct the system clock. This directive forces **chronyd** to step system clock if the adjustment is larger than a threshold value, but only if there were no more clock updates since **chronyd** was started than a specified limit (a negative value can be used to disable the limit). This is particularly useful when using reference clock, because the **initstepslew** directive only works with NTP sources.

An example of the use of this directive is:

```
makestep 1000 10
```
This would step the system clock if the adjustment is larger than 1000 seconds, but only in the first ten clock updates.

**maxchange**
This directive sets the maximum allowed offset corrected on a clock update. The check is performed only after the specified number of updates to allow a large initial adjustment of the system clock. When an offset larger than the specified maximum occurs, it will be ignored for the specified number of times and then **chronyd** will give up and exit (a negative value can be used to never exit). In both cases a message is sent to syslog.

An example of the use of this directive is:

```
maxchange 1000 1 2
```

After the first clock update, **chronyd** will check the offset on every clock update, it will ignore two adjustments larger than 1000 seconds and exit on another one.

**maxupdateskew**
One of **chronyd**'s tasks is to work out how fast or slow the computer's clock runs relative to its reference sources. In addition, it computes an estimate of the error bounds around the estimated value. If the range of error is too large, it indicates that the measurements have not settled down yet, and that the estimated gain or loss rate is not very reliable. The **maxupdateskew** parameter is the threshold for determining whether an estimate is too unreliable to be used. By default, the threshold is 1000 ppm. The format of the syntax is:

```
maxupdateskew skew-in-ppm
```

Typical values for *skew-in-ppm* might be 100 for a dial-up connection to servers over a telephone line, and 5 or 10 for a computer on a LAN. It should be noted that this is not the only means of protection against using unreliable estimates. At all times, **chronyd** keeps track of both the estimated gain or loss rate, and the error bound on the estimate. When a new estimate is generated following another measurement from one of the sources, a weighted combination algorithm is used to update the master estimate. So if **chronyd** has an existing highly-reliable master estimate and a new estimate is generated which has large error bounds, the existing master estimate will dominate in the new master estimate.

**minsources**
The **minsources** directive sets the minimum number of sources that need to be considered as selectable in the source selection algorithm before the local clock is updated.

The format of the syntax is:

```
minsources number-of-sources
```

By default, *number-of-sources* is 1. Setting minsources to a larger number can be used to improve the reliability, because multiple sources will need to correspond with each other.

**noclientlog**
This directive, which takes no arguments, specifies that client accesses are not to be logged. Normally they are logged, allowing statistics to be reported using the clients command in **chronyc**.

**reselectdist**
When `chronyd` selects synchronization source from available sources, it will prefer the one with minimum synchronization distance. However, to avoid frequent reselecting when there are sources with similar distance, a fixed distance is added to the distance for sources that are currently not selected. This can be set with the `reselectdist` option. By default, the distance is 100 microseconds.

The format of the syntax is:

```
reselectdist dist-in-seconds
```

**stratumweight**

The `stratumweight` directive sets how much distance should be added per stratum to the synchronization distance when `chronyd` selects the synchronization source from available sources.

The format of the syntax is:

```
stratumweight dist-in-seconds
```

By default, `dist-in-seconds` is 1 millisecond. This means that sources with lower stratum are usually preferred to sources with higher stratum even when their distance is significantly worse. Setting `stratumweight` to 0 makes `chronyd` ignore stratum when selecting the source.

**rtcfile**

The `rtcfile` directive defines the name of the file in which `chronyd` can save parameters associated with tracking the accuracy of the system's real-time clock (RTC). The format of the syntax is:

```
rtcfile /var/lib/chrony/rtc
```

`chronyd` saves information in this file when it exits and when the `writertc` command is issued in `chronyc`. The information saved is the RTC's error at some epoch, that epoch (in seconds since January 1 1970), and the rate at which the RTC gains or loses time. Not all real-time clocks are supported as their code is system-specific. Note that if this directive is used then the real-time clock should not be manually adjusted as this would interfere with `chrony`'s need to measure the rate at which the real-time clock drifts if it was adjusted at random intervals.

**rtcsync**

The `rtcsync` directive is present in the `/etc/chrony.conf` file by default. This will inform the kernel the system clock is kept synchronized and the kernel will update the real-time clock every 11 minutes.

### 16.2.4. Security with chronyc

Chronyc can access `chronyd` in two ways:

- Internet Protocol (IPv4 or IPv6,
- Unix domain socket, which is accessible locally by the root or chrony user.

By default, `chronyc` connects to the Unix domain socket. The default path is `/var/run/chrony/chronyd.sock`. If this connection fails, which can happen for example when
chronyc is running under a non-root user, chronyc tries to connect to 127.0.0.1 and then ::1.

Only the following monitoring commands, which do not affect the behavior of chronyd, are allowed from the network:

- activity
- manual list
- rtcdatal
- smoothing
- sources
- sourcestats
- tracking
- waitsync

The set of hosts from which chronyd accepts these commands can be configured with the cmdallow directive in the configuration file of chronyd, or the cmdallow command in chronyc. By default, the commands are accepted only from localhost (127.0.0.1 or ::1).

All other commands are allowed only through the Unix domain socket. When sent over the network, chronyd responds with a Not authorised error, even if it is from localhost.

Procedure 16.1. Accessing chronyd remotely with chronyc

1. Allow access from both IPv4 and IPv6 addresses by adding the following to the /etc/chrony.conf file:

   bindcmdaddress 0.0.0.0

   or

   bindcmdaddress :

2. Allow commands from the remote IP address, network, or subnet by using the cmdallow directive.

   Example 16.1.

   Add the following content to the /etc/chrony.conf file:

   cmdallow 192.168.1.0/24

3. Open port 323 in the firewall to connect from a remote system.

   ~]$ firewall-cmd --zone=public --add-port=323/udp

   If you want to open port 323 permanently, use the --permanent.
~]$ firewall-cmd --permanent --zone=public --add-port=323/udp

Note that the allow directive is for NTP access whereas the cmdallow directive is to enable receiving of remote commands. It is possible to make these changes temporarily using chronyc running locally. Edit the configuration file to make permanent changes.

16.3. USING CHRONY

16.3.1. Installing chrony

The chrony suite is installed by default on some versions of Red Hat Enterprise Linux 7. If required, to ensure that it is, run the following command as root:

~]$ yum install chrony

The default location for the chrony daemon is /usr/sbin/chronyd. The command line utility will be installed to /usr/bin/chronyc.

16.3.2. Checking the Status of chronyd

To check the status of chronyd, issue the following command:

~]$ systemctl status chronyd
chronyd.service - NTP client/server
   Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled)
   Active: active (running) since Wed 2013-06-12 22:23:16 CEST; 11h ago

16.3.3. Starting chronyd

To start chronyd, issue the following command as root:

~]$ systemctl start chronyd

To ensure chronyd starts automatically at system start, issue the following command as root:

~]$ systemctl enable chronyd

16.3.4. Stopping chronyd

To stop chronyd, issue the following command as root:

~]$ systemctl stop chronyd

To prevent chronyd from starting automatically at system start, issue the following command as root:

~]$ systemctl disable chronyd

16.3.5. Checking if chrony is Synchronized

CHAPTER 16. CONFIGURING NTP USING THE CHRONY SUITE
To check if chrony is synchronized, make use of the tracking, sources, and sourcestats commands.

### 16.3.5.1. Checking chrony Tracking

To check chrony tracking, issue the following command:

```bash
~]$ chronyc tracking
```

<table>
<thead>
<tr>
<th>Reference ID</th>
<th>CB00710F (foo.example.net)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stratum</td>
<td>3</td>
</tr>
<tr>
<td>Ref time (UTC)</td>
<td>Fri Jan 27 09:49:17 2017</td>
</tr>
<tr>
<td>System time</td>
<td>0.0000006523 seconds slow of NTP time</td>
</tr>
<tr>
<td>Last offset</td>
<td>-0.0000006747 seconds</td>
</tr>
<tr>
<td>RMS offset</td>
<td>0.000035822 seconds</td>
</tr>
<tr>
<td>Frequency</td>
<td>3.225 ppm slow</td>
</tr>
<tr>
<td>Residual freq</td>
<td>0.000 ppm</td>
</tr>
<tr>
<td>Skew</td>

</tr>
<tr>
<td>Update interval</td>
<td>64.2 seconds</td>
</tr>
<tr>
<td>Leap status</td>
<td>Normal</td>
</tr>
</tbody>
</table>

The fields are as follows:

#### Reference ID

This is the reference ID and name (or IP address) if available, of the server to which the computer is currently synchronized. Reference ID is a hexadecimal number to avoid confusion with IPv4 addresses.

#### Stratum

The stratum indicates how many hops away from a computer with an attached reference clock we are. Such a computer is a stratum-1 computer, so the computer in the example is two hops away (that is to say, a.b.c is a stratum-2 and is synchronized from a stratum-1).

#### Ref time

This is the time (UTC) at which the last measurement from the reference source was processed.

#### System time

In normal operation, chronyd never steps the system clock, because any jump in the timescale can have adverse consequences for certain application programs. Instead, any error in the system clock is corrected by slightly speeding up or slowing down the system clock until the error has been removed, and then returning to the system clock’s normal speed. A consequence of this is that there will be a period when the system clock (as read by other programs using the gettimeofday() system call, or by the date command in the shell) will be different from chronyd’s estimate of the current true time (which it reports to NTP clients when it is operating in server mode). The value reported on this line is the difference due to this effect.

#### Last offset

This is the estimated local offset on the last clock update.

#### RMS offset

This is a long-term average of the offset value.
Frequency

The “frequency” is the rate by which the system’s clock would be wrong if `chronyd` was not correcting it. It is expressed in ppm (parts per million). For example, a value of 1 ppm would mean that when the system’s clock thinks it has advanced 1 second, it has actually advanced by 1.000001 seconds relative to true time.

Residual freq

This shows the “residual frequency” for the currently selected reference source. This reflects any difference between what the measurements from the reference source indicate the frequency should be and the frequency currently being used. The reason this is not always zero is that a smoothing procedure is applied to the frequency. Each time a measurement from the reference source is obtained and a new residual frequency computed, the estimated accuracy of this residual is compared with the estimated accuracy (see skew next) of the existing frequency value. A weighted average is computed for the new frequency, with weights depending on these accuracies. If the measurements from the reference source follow a consistent trend, the residual will be driven to zero over time.

Skew

This is the estimated error bound on the frequency.

Root delay

This is the total of the network path delays to the stratum-1 computer from which the computer is ultimately synchronized. Root delay values are printed in nanosecond resolution. In certain extreme situations, this value can be negative. (This can arise in a symmetric peer arrangement where the computers’ frequencies are not tracking each other and the network delay is very short relative to the turn-around time at each computer.)

Root dispersion

This is the total dispersion accumulated through all the computers back to the stratum-1 computer from which the computer is ultimately synchronized. Dispersion is due to system clock resolution, statistical measurement variations etc. Root dispersion values are printed in nanosecond resolution.

Leap status

This is the leap status, which can be Normal, Insert second, Delete second or Not synchronized.

16.3.5.2. Checking chrony Sources

The sources command displays information about the current time sources that `chronyd` is accessing. The optional argument `-v` can be specified, meaning verbose. In this case, extra caption lines are shown as a reminder of the meanings of the columns.

```
[-]$ chronyc sources
210 Number of sources = 3
MS Name/IP address         Stratum Poll Reach LastRx Last sample
==========================================================================
===== 0                       134ns 0 4 377 11  -479ns[ -621ns] +/- 134ns
#* GPS0                        2 6 377 23  -923us[ -924us] +/-
```

CHAPTER 16. CONFIGURING NTP USING THE CHRONY SUITE

315
The columns are as follows:

M
This indicates the mode of the source. ^ means a server, = means a peer and # indicates a locally connected reference clock.

S
This column indicates the state of the sources. “*” indicates the source to which chronyd is currently synchronized. “+” indicates acceptable sources which are combined with the selected source. “-” indicates acceptable sources which are excluded by the combining algorithm. “?” indicates sources to which connectivity has been lost or whose packets do not pass all tests. “x” indicates a clock which chronyd thinks is a falseticker (its time is inconsistent with a majority of other sources). “~” indicates a source whose time appears to have too much variability. The “?” condition is also shown at start-up, until at least 3 samples have been gathered from it.

Name/IP address
This shows the name or the IP address of the source, or reference ID for reference clock.

Stratum
This shows the stratum of the source, as reported in its most recently received sample. Stratum 1 indicates a computer with a locally attached reference clock. A computer that is synchronized to a stratum 1 computer is at stratum 2. A computer that is synchronized to a stratum 2 computer is at stratum 3, and so on.

Poll
This shows the rate at which the source is being polled, as a base-2 logarithm of the interval in seconds. Thus, a value of 6 would indicate that a measurement is being made every 64 seconds. chronyd automatically varies the polling rate in response to prevailing conditions.

Reach
This shows the source's reach register printed as an octal number. The register has 8 bits and is updated on every received or missed packet from the source. A value of 377 indicates that a valid reply was received for all of the last eight transmissions.

LastRx
This column shows how long ago the last sample was received from the source. This is normally in seconds. The letters m, h, d or y indicate minutes, hours, days or years. A value of 10 years indicates there were no samples received from this source yet.

Last sample
This column shows the offset between the local clock and the source at the last measurement. The number in the square brackets shows the actual measured offset. This may be suffixed by ns (indicating nanoseconds), us (indicating microseconds), ms (indicating milliseconds), or s (indicating seconds). The number to the left of the square brackets shows the original measurement, adjusted to allow for any slews applied to the local clock since. The number following the +/- indicator shows the margin of error in the measurement. Positive offsets indicate that the local clock is ahead of the source.
16.3.5.3. Checking chrony Source Statistics

The `sourcestats` command displays information about the drift rate and offset estimation process for each of the sources currently being examined by `chronyd`. The optional argument `-v` can be specified, meaning verbose. In this case, extra caption lines are shown as a reminder of the meanings of the columns.

```
-]$ chronyc sourcestats
210 Number of sources = 1
Name/IP Address            NP  NR  Span  Frequency  Freq Skew  Offset Std Dev
==========================================================================
=====
abc.def.ghi                11   5   46m     -0.001      0.045      1us
25us
```

The columns are as follows:

Name/IP address

This is the name or IP address of the NTP server (or peer) or reference ID of the reference clock to which the rest of the line relates.

NP

This is the number of sample points currently being retained for the server. The drift rate and current offset are estimated by performing a linear regression through these points.

NR

This is the number of runs of residuals having the same sign following the last regression. If this number starts to become too small relative to the number of samples, it indicates that a straight line is no longer a good fit to the data. If the number of runs is too low, `chronyd` discards older samples and re-runs the regression until the number of runs becomes acceptable.

Span

This is the interval between the oldest and newest samples. If no unit is shown the value is in seconds. In the example, the interval is 46 minutes.

Frequency

This is the estimated residual frequency for the server, in parts per million. In this case, the computer's clock is estimated to be running 1 part in $10^9$ slow relative to the server.

Freq Skew

This is the estimated error bounds on Freq (again in parts per million).

Offset

This is the estimated offset of the source.

Std Dev

This is the estimated sample standard deviation.
16.3.6. Manually Adjusting the System Clock

To step the system clock immediately, bypassing any adjustments in progress by slewing, issue the following command as root:

```
~
]# chronyc makestep
```

If the `rtcfile` directive is used, the real-time clock should not be manually adjusted. Random adjustments would interfere with `chrony`'s need to measure the rate at which the real-time clock drifts.

16.4. SETTING UP CHRONY FOR DIFFERENT ENVIRONMENTS

16.4.1. Setting Up chrony for a System in an Isolated Network

For a network that is never connected to the Internet, one computer is selected to be the master timeserver. The other computers are either direct clients of the master, or clients of clients. On the master, the drift file must be manually set with the average rate of drift of the system clock. If the master is rebooted, it will obtain the time from surrounding systems and calculate an average to set its system clock. Thereafter it resumes applying adjustments based on the drift file. The drift file will be updated automatically when the `settime` command is used.

On the system selected to be the master, using a text editor running as root, edit the `/etc/chrony.conf` as follows:

```
driftfile /var/lib/chrony/drift
commandkey 1
keyfile /etc/chrony.keys
initstepslew 10 client1 client3 client6
local stratum 8
manual
allow 192.0.2.0
```

Where `192.0.2.0` is the network or subnet address from which the clients are allowed to connect.

On the systems selected to be direct clients of the master, using a text editor running as root, edit the `/etc/chrony.conf` as follows:

```
server master
driftfile /var/lib/chrony/drift
logdir /var/log/chrony
log measurements statistics tracking
keyfile /etc/chrony.keys
commandkey 24
local stratum 10
initstepslew 20 master
allow 192.0.2.123
```

Where `192.0.2.123` is the address of the master, and `master` is the host name of the master. Clients with this configuration will resynchronize the master if it restarts.

On the client systems which are not to be direct clients of the master, the `/etc/chrony.conf` file should be the same except that the `local` and `allow` directives should be omitted.
In an Isolated Network, you can also use the `local` directive that enables a local reference mode, which allows `chronyd` operating as an NTP server to appear synchronized to real time, even when it was never synchronized or the last update of the clock happened a long time ago.

To allow multiple servers in the network to use the same local configuration and to be synchronized to one another, without confusing clients that poll more than one server, use the `orphan` option of the `local` directive which enables the orphan mode. Each server needs to be configured to poll all other servers with `local`. This ensures that only the server with the smallest reference ID has the local reference active and other servers are synchronized to it. When the server fails, another one will take over.

### 16.5. USING CHRONYC

#### 16.5.1. Using chronyc to Control chronyd

To make changes to the local instance of `chronyd` using the command line utility `chronyc` in interactive mode, enter the following command as `root`:

```
[~]# chronyc
```

`chronyc` must run as `root` if some of the restricted commands are to be used.

The `chronyc` command prompt will be displayed as follows:

```
chronyc>
```

You can type `help` to list all of the commands.

The utility can also be invoked in non-interactive command mode if called together with a command as follows:

```
chronyc command
```

**NOTE**

Changes made using `chronyc` are not permanent, they will be lost after a `chronyd` restart. For permanent changes, modify `/etc/chrony.conf`.

### 16.6. CHRONY WITH HW TIME-STAMPING

#### 16.6.1. Understanding Hardware Timestamping

Hardware timestamping is a feature supported in some Network Interface Controller (NICs) which provides accurate timestamping of incoming and outgoing packets. NTP timestamps are usually created by the kernel and `chronyd` with the use of the system clock. However, when HW timestamping is enabled, the NIC uses its own clock to generate the timestamps when packets are entering or leaving the link layer or the physical layer. When used with NTP, hardware timestamping can significantly improve the accuracy of synchronization. For best accuracy, both NTP servers and NTP clients need to use hardware timestamping. Under ideal conditions, a sub-microsecond accuracy may be possible.
Another protocol for time synchronization that uses hardware timestamping is PTP. For further information about PTP, see Chapter 18, Configuring PTP Using ptp4l. Unlike NTP, PTP relies on assistance in network switches and routers. If you want to reach the best accuracy of synchronization, use PTP on networks that have switches and routers with PTP support, and prefer NTP on networks that do not have such switches and routers.

16.6.2. Verifying Support for Hardware Timestamping

To verify that hardware timestamping with NTP is supported by an interface, use the `ethtool -T` command. An interface can be used for hardware timestamping with NTP if `ethtool` lists the `SOF_TIMESTAMPING_TX_HARDWARE` and `SOF_TIMESTAMPING_TX_SOFTWARE` capabilities and also the `HWTSTAMP_FILTER_ALL` filter mode.

**Example 16.2. Verifying Support for Hardware Timestamping on a Specific Interface**

```bash
~]$ ethtool -T eth0
```

Output:

```
Timestamping parameters for eth0:
Capabilities:
  hardware-transmit     (SOF_TIMESTAMPING_TX_HARDWARE)
  software-transmit     (SOF_TIMESTAMPING_TX_SOFTWARE)
  hardware-receive      (SOF_TIMESTAMPING_RX_HARDWARE)
  software-receive      (SOF_TIMESTAMPING_RX_SOFTWARE)
  software-system-clock (SOF_TIMESTAMPING_SOFTWARE)
  hardware-raw-clock    (SOF_TIMESTAMPING_RAW_HARDWARE)

PTP Hardware Clock: 0
Hardware Transmit Timestamp Modes:
  off                   (HWTSTAMP_TX_OFF)
  on                    (HWTSTAMP_TX_ON)
Hardware Receive Filter Modes:
  none                  (HWTSTAMP_FILTER_NONE)
  all                   (HWTSTAMP_FILTER_ALL)
  ptpv1-l4-sync         (HWTSTAMP_FILTER_PTP_V1_L4_SYNC)
  ptpv1-l4-delay-req    (HWTSTAMP_FILTER_PTP_V1_L4_DELAY_REQ)
  ptpv2-l4-sync         (HWTSTAMP_FILTER_PTP_V2_L4_SYNC)
  ptpv2-l4-delay-req    (HWTSTAMP_FILTER_PTP_V2_L4_DELAY_REQ)
  ptpv2-l2-sync         (HWTSTAMP_FILTER_PTP_V2_L2_SYNC)
  ptpv2-l2-delay-req    (HWTSTAMP_FILTER_PTP_V2_L2_DELAY_REQ)
  ptpv2-event           (HWTSTAMP_FILTER_PTP_V2_EVENT)
  ptpv2-sync            (HWTSTAMP_FILTER_PTP_V2_SYNC)
  ptpv2-delay-req       (HWTSTAMP_FILTER_PTP_V2_DELAY_REQ)
```

16.6.3. Enabling Hardware Timestamping

To enable hardware timestamping, use the `hwtimestamp` directive in the `/etc/chrony.conf` file. The directive can either specify a single interface, or a wildcard character (*) can be used to enable hardware timestamping on all interfaces that support it. Use the wildcard specification in case that no other application, like ptp4l from the linuxptp package, is using hardware timestamping on an interface. Multiple `hwtimestamp` directives are allowed in the chrony configuration file.
Example 16.3. Enabling Hardware Timestamping by Using the hwtimestamp Directive

```
hwtimestamp eth0
hwtimestamp eth1
hwtimestamp *
```

16.6.4. Configuring Client Polling Interval

The default range of a polling interval (64-1024 seconds) is recommended for servers on the Internet. For local servers and hardware timestamping, a shorter polling interval needs to be configured in order to minimize offset of the system clock.

The following directive in `/etc/chrony.conf` specifies a local NTP server using one second polling interval:

```
server ntp.local minpoll 0 maxpoll 0
```

16.6.5. Enabling Interleaved Mode

NTP servers that are not hardware NTP appliances, but rather general purpose computers running a software NTP implementation, like `chrony`, will get a hardware transmit timestamp only after sending a packet. This behavior prevents the server from saving the timestamp in the packet to which it corresponds. In order to enable NTP clients receiving transmit timestamps that were generated after the transmission, configure the clients to use the NTP interleaved mode by adding the `xleave` option to the server directive in `/etc/chrony.conf`:

```
server ntp.local minpoll 0 maxpoll 0 xleave
```

16.6.6. Configuring Server for Large Number of Clients

The default server configuration allows a few thousands of clients at most to use the interleaved mode concurrently. To configure the server for a larger number of clients, increase the `clientloglimit` directive in `/etc/chrony.conf`. This directive specifies the maximum size of memory allocated for logging of clients' access on the server:

```
clientloglimit 100000000
```

16.6.7. Verifying Hardware Timestamping

To verify that the interface has successfully enabled hardware timestamping, check the system log. The log should contain a message from `chronyd` for each interface with successfully enabled hardware timestamping.

Example 16.4. Log Messages for Interfaces with Enabled Hardware Timestamping

```
chronyd[4081]: Enabled HW timestamping on eth0
chronyd[4081]: Enabled HW timestamping on eth1
```
When \texttt{chronyd} is configured as an NTP client or peer, you can have the transmit and receive timestamping modes and the interleaved mode reported for each NTP source by the \texttt{chronyc ntpdata} command:

\textbf{Example 16.5. Reporting the Transmit, Receive Timestamping and Interleaved Mode for Each NTP Source}

```
~]$# chronyc ntpdata
```

\textbf{Output:}

- Remote address : 203.0.113.15 (CB00710F)
- Remote port    : 123
- Local address  : 203.0.113.74 (CB00714A)
- Leap status    : Normal
- Version        : 4
- Mode           : Server
- Stratum        : 1
- Poll interval  : 0 (1 seconds)
- Precision      : -24 (0.000000060 seconds)
- Root delay     : 0.000015 seconds
- Root dispersion: 0.000015 seconds
- Reference ID   : 47505300 (GPS)
- Reference time : Wed May 03 13:47:45 2017
- Offset         : -0.000000134 seconds
- Peer delay     : 0.00005396 seconds
- Peer dispersion: 0.00002329 seconds
- Response time  : 0.000152073 seconds
- Jitter asymmetry: +0.00
- NTP tests      : 111 111 1111
- Interleaved    : Yes
- Authenticated  : No
- TX timestamping: Hardware
- RX timestamping: Hardware
- Total TX       : 27
- Total RX       : 27
- Total valid RX : 27

\textbf{Example 16.6. Reporting the Stability of NTP Measurements}

```
# chronyc sourcestats
```

With hardware timestamping enabled, stability of NTP measurements should be in tens or hundreds of nanoseconds, under normal load. This stability is reported in the \texttt{Std Dev} column of the output of the \texttt{chronyc sourcestats} command:

\textbf{Output:}

```
210 Number of sources = 1
Name/IP Address    NP  NR  Span  Frequency  Freq Skew  Offset
ntp.local          12  7   11   +0.000     0.019   +0ns
```
16.6.8. Configuring PTP-NTP bridge

If a highly accurate Precision Time Protocol (PTP) grandmaster is available in a network that does not have switches or routers with PTP support, a computer may be dedicated to operate as a PTP slave and a stratum-1 NTP server. Such a computer needs to have two or more network interfaces, and be close to the grandmaster or have a direct connection to it. This will ensure highly accurate synchronization in the network.

Configure the ptp4l and phc2sys programs from the linuxptp packages to use one interface to synchronize the system clock using PTP. The configuration is described in the Chapter 18, Configuring PTP Using ptp4l. Configure chronyd to provide the system time using the other interface:

Example 16.7. Configuring chronyd to Provide the System Time Using the Other Interface

bindaddress 203.0.113.74
hwtimestamp eth1
local stratum 1

16.7. ADDITIONAL RESOURCES

The following sources of information provide additional resources regarding chrony.

16.7.1. Installed Documentation

- chronyc(1) man page – Describes the chronyc command-line interface tool including commands and command options.
- chronyd(8) man page – Describes the chronyd daemon including commands and command options.
- chrony.conf(5) man page – Describes the chrony configuration file.

16.7.2. Online Documentation

For answers to FAQs, see http://chrony.tuxfamily.org/faq.html
CHAPTER 17. CONFIGURING NTP USING NTPD

17.1. INTRODUCTION TO NTP

The Network Time Protocol (NTP) enables the accurate dissemination of time and date information in order to keep the time clocks on networked computer systems synchronized to a common reference over the network or the Internet. Many standards bodies around the world have atomic clocks which may be made available as a reference. The satellites that make up the Global Position System contain more than one atomic clock, making their time signals potentially very accurate. Their signals can be deliberately degraded for military reasons. An ideal situation would be where each site has a server, with its own reference clock attached, to act as a site-wide time server. Many devices which obtain the time and date via low frequency radio transmissions or the Global Position System (GPS) exist. However for most situations, a range of publicly accessible time servers connected to the Internet at geographically dispersed locations can be used. These NTP servers provide “Coordinated Universal Time” (UTC). Information about these time servers can found at www.pool.ntp.org.

Accurate time keeping is important for a number of reasons in IT. In networking for example, accurate time stamps in packets and logs are required. Logs are used to investigate service and security issues and so time stamps made on different systems must be made by synchronized clocks to be of real value. As systems and networks become increasingly faster, there is a corresponding need for clocks with greater accuracy and resolution. In some countries there are legal obligations to keep accurately synchronized clocks. Please see www.ntp.org for more information. In Linux systems, NTP is implemented by a daemon running in user space. The default NTP user space daemon in Red Hat Enterprise Linux 7 is chronyd. It must be disabled if you want to use the ntpd daemon. See Chapter 16, Configuring NTP Using the chrony Suite for information on chrony.

The user space daemon updates the system clock, which is a software clock running in the kernel. Linux uses a software clock as its system clock for better resolution than the typical embedded hardware clock referred to as the “Real Time Clock” (RTC). See the rtc(4) and hwclock(8) man pages for information on hardware clocks. The system clock can keep time by using various clock sources. Usually, the Time Stamp Counter (TSC) is used. The TSC is a CPU register which counts the number of cycles since it was last reset. It is very fast, has a high resolution, and there are no interrupts. On system start, the system clock reads the time and date from the RTC. The time kept by the RTC will drift away from actual time by up to 5 minutes per month due to temperature variations. Hence the need for the system clock to be constantly synchronized with external time references. When the system clock is being synchronized by ntpd, the kernel will in turn update the RTC every 11 minutes automatically.

17.2. NTP STRATA

NTP servers are classified according to their synchronization distance from the atomic clocks which are the source of the time signals. The servers are thought of as being arranged in layers, or strata, from 1 at the top down to 15. Hence the word stratum is used when referring to a specific layer. Atomic clocks are referred to as Stratum 0 as this is the source, but no Stratum 0 packet is sent on the Internet, all stratum 0 atomic clocks are attached to a server which is referred to as stratum 1. These servers send out packets marked as Stratum 1. A server which is synchronized by means of packets marked stratum n belongs to the next, lower, stratum and will mark its packets as stratum n+1. Servers of the same stratum can exchange packets with each other but are still designated as belonging to just the one stratum, the stratum one below the best reference they are synchronized to. The designation Stratum 16 is used to indicate that the server is not currently synchronized to a reliable time source.

Note that by default NTP clients act as servers for those systems in the stratum below them.
Here is a summary of the NTP Strata:

**Stratum 0:**
Atomic Clocks and their signals broadcast over Radio and GPS
- GPS (Global Positioning System)
- Mobile Phone Systems
- Low Frequency Radio Broadcasts WWVB (Colorado, USA.), JJY-40 and JJY-60 (Japan), DCF77 (Germany), and MSF (United Kingdom)

These signals can be received by dedicated devices and are usually connected by RS-232 to a system used as an organizational or site-wide time server.

**Stratum 1:**
Computer with radio clock, GPS clock, or atomic clock attached

**Stratum 2:**
Reads from stratum 1; Serves to lower strata

**Stratum 3:**
Reads from stratum 2; Serves to lower strata

**Stratum n+1:**
Reads from stratum n; Serves to lower strata

**Stratum 15:**
Reads from stratum 14; This is the lowest stratum.

This process continues down to Stratum 15 which is the lowest valid stratum. The label Stratum 16 is used to indicated an unsynchronized state.

### 17.3. UNDERSTANDING NTP

This implementation of NTP enables sub-second accuracy to be achieved. Over the Internet, accuracy to 10s of milliseconds is normal. On a Local Area Network (LAN), 1 ms accuracy is possible under ideal conditions. This is because clock drift is now accounted and corrected for, which was not done in earlier, simpler, time protocol systems. A resolution of 233 picoseconds is provided by using 64-bit time stamps. The first 32-bits of the time stamp is used for seconds, the last 32-bits are used for fractions of seconds.

NTP represents the time as a count of the number of seconds since 00:00 (midnight) 1 January, 1900 GMT. As 32-bits is used to count the seconds, this means the time will “roll over” in 2036. However NTP works on the difference between time stamps so this does not present the same level of problem as other implementations of time protocols have done. If a hardware clock that is within 68 years of the correct time is available at boot time then NTP will correctly interpret the current date. The NTP4
The specification provides for an “Era Number” and an “Era Offset” which can be used to make software more robust when dealing with time lengths of more than 68 years. Note, please do not confuse this with the Unix Year 2038 problem.

The NTP protocol provides additional information to improve accuracy. Four time stamps are used to allow the calculation of round-trip time and server response time. In order for a system in its role as NTP client to synchronize with a reference time server, a packet is sent with an “originate time stamp”. When the packet arrives, the time server adds a “receive time stamp”. After processing the request for time and date information and just before returning the packet, it adds a “transmit time stamp”. When the returning packet arrives at the NTP client, a “receive time stamp” is generated. The client can now calculate the total round trip time and by subtracting the processing time derive the actual traveling time. By assuming the outgoing and return trips take equal time, the single-trip delay in receiving the NTP data is calculated. The full NTP algorithm is much more complex than presented here.

When a packet containing time information is received it is not immediately responded to, but is first subject to validation checks and then processed together with several other time samples to arrive at an estimate of the time. This is then compared to the system clock to determine the time offset, the difference between the system clock’s time and what ntpd has determined the time should be. The system clock is adjusted slowly, at most at a rate of 0.5 ms per second, to reduce this offset by changing the frequency of the counter being used. It will take at least 2000 seconds to adjust the clock by 1 second using this method. This slow change is referred to as slewing and cannot go backwards. If the time offset of the clock is more than 128 ms (the default setting), ntpd can “step” the clock forwards or backwards. If the time offset at system start is greater than 1000 seconds then the user, or an installation script, should make a manual adjustment. See Chapter 2, Configuring the Date and Time. With the -g option to the ntpd command (used by default), any offset at system start will be corrected, but during normal operation only offsets of up to 1000 seconds will be corrected.

Some software may fail or produce an error if the time is changed backwards. For systems that are sensitive to step changes in the time, the threshold can be changed to 600 s instead of 128 ms using the -x option (unrelated to the -g option). Using the -x option to increase the stepping limit from 0.128 s to 600 s has a drawback because a different method of controlling the clock has to be used. It disables the kernel clock discipline and may have a negative impact on the clock accuracy. The -x option can be added to the /etc/sysconfig/ntpd configuration file.

17.4. UNDERSTANDING THE DRIFT FILE

The drift file is used to store the frequency offset between the system clock running at its nominal frequency and the frequency required to remain in synchronization with UTC. If present, the value contained in the drift file is read at system start and used to correct the clock source. Use of the drift file reduces the time required to achieve a stable and accurate time. The value is calculated, and the drift file replaced, once per hour by ntpd. The drift file is replaced, rather than just updated, and for this reason the drift file must be in a directory for which the ntpd has write permissions.

17.5. UTC, TIMEZONES, AND DST

As NTP is entirely in UTC (Universal Time, Coordinated), Timezones and DST (Daylight Saving Time) are applied locally by the system. The file /etc/localtime is a copy of, or symlink to, a zone information file from /usr/share/zoneinfo. The RTC may be in localtime or in UTC, as specified by the 3rd line of /etc/adjtime, which will be one of LOCAL or UTC to indicate how the RTC clock has been set. Users can easily change this setting using the checkbox System Clock Uses UTC in the Date and Time graphical configuration tool. See Chapter 2, Configuring the Date and Time for information on how to use that tool. Running the RTC in UTC is recommended to avoid various problems when daylight saving time is changed.
The operation of ntpd is explained in more detail in the man page ntpd(8). The resources section lists useful sources of information. See Section 17.20, “Additional Resources”.

17.6. AUTHENTICATION OPTIONS FOR NTP

NTPv4 NTPv4 added support for the Autokey Security Architecture, which is based on public asymmetric cryptography while retaining support for symmetric key cryptography. The Autokey protocol is described in RFC 5906 Network Time Protocol Version 4: Autokey Specification. Unfortunately, it was found later that the protocol has serious security issues, and thus Red Hat strongly recommends to use symmetric keys instead. The man page ntp_auth(5) describes the authentication options and commands for ntpd.

An attacker on the network can attempt to disrupt a service by sending NTP packets with incorrect time information. On systems using the public pool of NTP servers, this risk is mitigated by having more than three NTP servers in the list of public NTP servers in /etc/ntp.conf. If only one time source is compromised or spoofed, ntpd will ignore that source. You should conduct a risk assessment and consider the impact of incorrect time on your applications and organization. If you have internal time sources you should consider steps to protect the network over which the NTP packets are distributed. If you conduct a risk assessment and conclude that the risk is acceptable, and the impact to your applications minimal, then you can choose not to use authentication.

The broadcast and multicast modes require authentication by default. If you have decided to trust the network then you can disable authentication by using disable auth directive in the ntp.conf file. Alternatively, authentication needs to be configured by using SHA1 or MD5 symmetric keys, or by public (asymmetric) key cryptography using the Autokey scheme. The Autokey scheme for asymmetric cryptography is explained in the ntp_auth(5) man page and the generation of keys is explained in ntp-keygen(8). To implement symmetric key cryptography, see Section 17.17.12, “Configuring Symmetric Authentication Using a Key” for an explanation of the key option.

17.7. MANAGING THE TIME ON VIRTUAL MACHINES

Virtual machines cannot access a real hardware clock and a virtual clock is not stable enough as the stability is dependent on the host systems work load. For this reason, para-virtualized clocks should be provided by the virtualization application in use. On Red Hat Enterprise Linux with KVM the default clock source is kvm-clock. See the KVM guest timing management chapter of the Red Hat Enterprise Linux 7 Virtualization Deployment and Administration Guide.

17.8. UNDERSTANDING LEAP SECONDS

Greenwich Mean Time (GMT) was derived by measuring the solar day, which is dependent on the Earth's rotation. When atomic clocks were first made, the potential for more accurate definitions of time became possible. In 1958, International Atomic Time (TAI) was introduced based on the more accurate and very stable atomic clocks. A more accurate astronomical time, Universal Time 1 (UT1), was also introduced to replace GMT. The atomic clocks are in fact far more stable than the rotation of the Earth and so the two times began to drift apart. For this reason UTC was introduced as a practical measure. It is kept within one second of UT1 but to avoid making many small trivial adjustments it was decided to introduce the concept of a leap second in order to reconcile the difference in a manageable way. The difference between UT1 and UTC is monitored until they drift apart by more than half a second. Then only is it deemed necessary to introduce a one second adjustment, forward or backward. Due to the erratic nature of the Earth's rotational speed, the need for an adjustment cannot be predicted far into the future. The decision as to when to make an adjustment is made by the International Earth Rotation and Reference Systems Service (IERS). However, these announcements are important only to administrators of Stratum 1 servers because NTP transmits information about pending leap seconds and applies them automatically.
17.9. UNDERSTANDING THE NTPD CONFIGURATION FILE

The daemon, ntpd, reads the configuration file at system start or when the service is restarted. The default location for the file is /etc/ntp.conf and you can view the file by entering the following command:

```bash
$ less /etc/ntp.conf
```

The configuration commands are explained briefly later in this chapter, see Section 17.17, “Configure NTP”, and more verbosely in the ntp.conf(5) man page.

Here follows a brief explanation of the contents of the default configuration file:

The driftfile entry

A path to the drift file is specified, the default entry on Red Hat Enterprise Linux is:

```plaintext
driftfile /var/lib/ntp/drift
```

If you change this be certain that the directory is writable by ntpd. The file contains one value used to adjust the system clock frequency after every system or service start. See Understanding the Drift File for more information.

The access control entries

The following line sets the default access control restriction:

```plaintext
restrict default nomodify notrap nopeer noquery
```

- The nomodify option prevents any changes to the configuration.
- The notrap option prevents ntpdc control message protocol traps.
- The nopeer option prevents a peer association being formed.
- The noquery option prevents ntpq and ntpdc queries, but not time queries, from being answered.

**IMPORTANT**

The ntpq and ntpdc queries can be used in amplification attacks, therefore do not remove the noquery option from the restrict default command on publicly accessible systems.

See CVE-2013-5211 for more details.

Addresses within the range 127.0.0.0/8 are sometimes required by various processes or applications. As the "restrict default" line above prevents access to everything not explicitly allowed, access to the standard loopback address for IPv4 and IPv6 is permitted by means of the following lines:

```plaintext
# the administrative functions.
restrict 127.0.0.1
restrict ::1
```
Addresses can be added underneath if specifically required by another application.

Hosts on the local network are not permitted because of the "restrict default" line above. To change this, for example to allow hosts from the 192.0.2.0/24 network to query the time and statistics but nothing more, a line in the following format is required:

```
restrict 192.0.2.0 mask 255.255.255.0 nomodify notrap nopeer
```

To allow unrestricted access from a specific host, for example 192.0.2.250/32, a line in the following format is required:

```
restrict 192.0.2.250
```

A mask of 255.255.255.255 is applied if none is specified.

The restrict commands are explained in the ntp_acc(5) man page.

**The public servers entry**

By default, the ntp.conf file contains four public server entries:

```
server 0.rhel.pool.ntp.org iburst
server 1.rhel.pool.ntp.org iburst
server 2.rhel.pool.ntp.org iburst
server 3.rhel.pool.ntp.org iburst
```

**The broadcast multicast servers entry**

By default, the ntp.conf file contains some commented out examples. These are largely self explanatory. See Section 17.17, “Configure NTP” for the explanation of the specific commands. If required, add your commands just below the examples.

```
# Command line options for ntpd
OPTIONS="-g"
```

**17.10. UNDERSTANDING THE NTPD SYSCONFIG FILE**

The file will be read by the ntpd init script on service start. The default contents is as follows:

```
When the DHCP client program, dhclient, receives a list of NTP servers from the DHCP server, it adds them to ntp.conf and restarts the service. To disable that feature, add PEERNTP=no to /etc/sysconfig/network.

**17.11. DISABLING CHRONY**
In order to use ntpd the default user space daemon, chronyd, must be stopped and disabled. Issue the following command as root:

```
~]# systemctl stop chronyd
```

To prevent it restarting at system start, issue the following command as root:

```
~]# systemctl disable chronyd
```

To check the status of chronyd, issue the following command:

```
~]$ systemctl status chronyd
```

### 17.12. CHECKING IF THE NTP DAEMON IS INSTALLED

To check if ntpd is installed, enter the following command as root:

```
~]# yum install ntp
```

NTP is implemented by means of the daemon or service ntpd, which is contained within the ntp package.

### 17.13. INSTALLING THE NTP DAEMON (NTPD)

To install ntpd, enter the following command as root:

```
~]# yum install ntp
```

To enable ntpd at system start, enter the following command as root:

```
~]# systemctl enable ntpd
```

### 17.14. CHECKING THE STATUS OF NTP

To check if ntpd is running and configured to run at system start, issue the following command:

```
~]$ systemctl status ntpd
```

To obtain a brief status report from ntpd, issue the following command:

```
~]$ ntpstat
unsynchronised
   time server re-starting
   polling server every 64 s

~]$ ntpstat
synchronised to NTP server (10.5.26.10) at stratum 2
   time correct to within 52 ms
   polling server every 1024 s
```
17.15. CONFIGURE THE FIREWALL TO ALLOW INCOMING NTP PACKETS

The NTP traffic consists of UDP packets on port 123 and needs to be permitted through network and host-based firewalls in order for NTP to function.

Check if the firewall is configured to allow incoming NTP traffic for clients using the graphical Firewall Configuration tool.

To start the graphical firewall-config tool, press the Super key to enter the Activities Overview, type firewall and then press Enter. The Firewall Configuration window opens. You will be prompted for your user password.

To start the graphical firewall configuration tool using the command line, enter the following command as root user:

```bash
~]$ firewall-config
```

The Firewall Configuration window opens. Note, this command can be run as normal user but you will then be prompted for the root password from time to time.

Look for the word “Connected” in the lower left corner. This indicates that the firewall-config tool is connected to the user space daemon, firewalld.

17.15.1. Change the Firewall Settings

To immediately change the current firewall settings, ensure the drop-down selection menu labeled Configuration is set to Runtime. Alternatively, to edit the settings to be applied at the next system start, or firewall reload, select Permanent from the drop-down list.

**NOTE**

When making changes to the firewall settings in Runtime mode, your selection takes immediate effect when you set or clear the check box associated with the service. You should keep this in mind when working on a system that may be in use by other users.

When making changes to the firewall settings in Permanent mode, your selection will only take effect when you reload the firewall or the system restarts. To reload the firewall, select the Options menu and select Reload Firewall.

17.15.2. Open Ports in the Firewall for NTP Packets

To permit traffic through the firewall to a certain port, start the firewall-config tool and select the network zone whose settings you want to change. Select the Ports tab and then click the Add button. The Port and Protocol window opens.

Enter the port number 123 and select udp from the drop-down list.

17.16. CONFIGURE NTPDATE SERVERS

The purpose of the ntpdate service is to set the clock during system boot. This was used previously to ensure that the services started after ntpdate would have the correct time and not observe a jump in the clock. The use of ntpdate and the list of step-tickers is considered deprecated and so Red Hat Enterprise Linux 7 uses the -g option to the ntpd command and not ntpdate by default.
The `ntpd` service in Red Hat Enterprise Linux 7 is mostly useful only when used alone without `ntpd`. With systemd, which starts services in parallel, enabling the `ntpd` service will not ensure that other services started after it will have correct time unless they specify an ordering dependency on `time-sync.target`, which is provided by the `ntpdate` service. In order to ensure a service starts with correct time, add `After=time-sync.target` to the service and enable one of the services which provide the target (`ntpdate` or `sntp`). Some services on Red Hat Enterprise Linux 7 have the dependency included by default (for example, `dhcpd`, `dhcpd6`, and `crond`).

To check if the `ntpdate` service is enabled to run at system start, issue the following command:

```
~$ systemctl status ntpdate
```

To enable the service to run at system start, issue the following command as `root`:

```
~# systemctl enable ntpdate
```

In Red Hat Enterprise Linux 7 the default `/etc/ntp/step-tickers` file contains `0.rhel.pool.ntp.org`. To configure additional `ntpdate` servers, using a text editor running as `root`, edit `/etc/ntp/step-tickers`. The number of servers listed is not very important as `ntpdate` will only use this to obtain the date information once when the system is starting. If you have an internal time server then use that host name for the first line. An additional host on the second line as a backup is sensible. The selection of backup servers and whether the second host is internal or external depends on your risk assessment. For example, what is the chance of any problem affecting the first server also affecting the second server? Would connectivity to an external server be more likely to be available than connectivity to internal servers in the event of a network failure disrupting access to the first server?

### 17.17. CONFIGURE NTP

To change the default configuration of the NTP service, use a text editor running as `root` user to edit the `/etc/ntp.conf` file. This file is installed together with `ntpd` and is configured to use time servers from the Red Hat pool by default. The man page `ntp.conf(5)` describes the command options that can be used in the configuration file apart from the access and rate limiting commands which are explained in the `ntp_acc(5)` man page.

#### 17.17.1. Configure Access Control to an NTP Service

To restrict or control access to the NTP service running on a system, make use of the `restrict` command in the `ntp.conf` file. See the commented out example:

```
# Hosts on local network are less restricted.
#restrict 192.168.1.0 mask 255.255.255.0 nomodify notrap
```

The `restrict` command takes the following form:

```
restrict option
```

where `option` is one or more of:

- `ignore` — All packets will be ignored, including `ntpq` and `ntpdc` queries.
- `kod` — a “Kiss-o'-death” packet is to be sent to reduce unwanted queries.
- **limited** — do not respond to time service requests if the packet violates the rate limit default values or those specified by the `discard` command. `ntpq` and `ntpdc` queries are not affected. For more information on the `discard` command and the default values, see Section 17.17.2, “Configure Rate Limiting Access to an NTP Service”.

- **lowpriotrap** — traps set by matching hosts to be low priority.

- **nomodify** — prevents any changes to the configuration.

- **noquery** — prevents `ntpq` and `ntpdc` queries, but not time queries, from being answered.

- **nopeer** — prevents a peer association being formed.

- **noserve** — deny all packets except `ntpq` and `ntpdc` queries.

- **notrap** — prevents `ntpdc` control message protocol traps.

- **notrust** — deny packets that are not cryptographically authenticated.

- **ntpport** — modify the match algorithm to only apply the restriction if the source port is the standard NTP UDP port 123.

- **version** — deny packets that do not match the current NTP version.

To configure rate limit access to not respond at all to a query, the respective `restrict` command has to have the **limited** option. If `ntpd` should reply with a KoD packet, the `restrict` command needs to have both **limited** and **kod** options.

The `ntpq` and `ntpdc` queries can be used in amplification attacks (see [CVE-2013-5211](#) for more details), do not remove the **noquery** option from the `restrict` default command on publicly accessible systems.

### 17.17.2. Configure Rate Limiting Access to an NTP Service

To enable rate limiting access to the NTP service running on a system, add the **limited** option to the `restrict` command as explained in Section 17.17.1, “Configure Access Control to an NTP Service”. If you do not want to use the default discard parameters, then also use the `discard` command as explained here.

The `discard` command takes the following form:

```
 discard [average value] [minimum value] [monitor value]
```

- **average** — specifies the minimum average packet spacing to be permitted, it accepts an argument in $\log_2$ seconds. The default value is 3 ($2^3$ equates to 8 seconds).

- **minimum** — specifies the minimum packet spacing to be permitted, it accepts an argument in $\log_2$ seconds. The default value is 1 ($2^1$ equates to 2 seconds).

- **monitor** — specifies the discard probability for packets once the permitted rate limits have been exceeded. The default value is 3000 seconds. This option is intended for servers that receive 1000 or more requests per second.

Examples of the `discard` command are as follows:
17.17.3. Adding a Peer Address

To add the address of a peer, that is to say, the address of a server running an NTP service of the same stratum, make use of the peer command in the ntp.conf file.

The peer command takes the following form:

```
peer address
```

where `address` is an IP unicast address or a DNS resolvable name. The address must only be that of a system known to be a member of the same stratum. Peers should have at least one time source that is different to each other. Peers are normally systems under the same administrative control.

17.17.4. Adding a Server Address

To add the address of a server, that is to say, the address of a server running an NTP service of a higher stratum, make use of the server command in the ntp.conf file.

The server command takes the following form:

```
server address
```

where `address` is an IP unicast address or a DNS resolvable name. The address of a remote reference server or local reference clock from which packets are to be received.

17.17.5. Adding a Broadcast or Multicast Server Address

To add a broadcast or multicast address for sending, that is to say, the address to broadcast or multicast NTP packets to, make use of the broadcast command in the ntp.conf file.

The broadcast and multicast modes require authentication by default. See Section 17.6, "Authentication Options for NTP".

The broadcast command takes the following form:

```
broadcast address
```

where `address` is an IP broadcast or multicast address to which packets are sent.

This command configures a system to act as an NTP broadcast server. The address used must be a broadcast or a multicast address. Broadcast address implies the IPv4 address 255.255.255.255. By default, routers do not pass broadcast messages. The multicast address can be an IPv4 Class D address, or an IPv6 address. The IANA has assigned IPv4 multicast address 224.0.1.1 and IPv6 address FF05::101 (site local) to NTP. Administratively scoped IPv4 multicast addresses can also be used, as described in RFC 2365 Administratively Scoped IP Multicast.

17.17.6. Adding a Manycast Client Address
To add a manycast client address, that is to say, to configure a multicast address to be used for NTP server discovery, make use of the `manycastclient` command in the `ntp.conf` file.

The `manycastclient` command takes the following form:

```
manycastclient address
```

where `address` is an IP multicast address from which packets are to be received. The client will send a request to the address and select the best servers from the responses and ignore other servers. NTP communication then uses unicast associations, as if the discovered NTP servers were listed in `ntp.conf`.

This command configures a system to act as an NTP client. Systems can be both client and server at the same time.

### 17.17.7. Adding a Broadcast Client Address

To add a broadcast client address, that is to say, to configure a broadcast address to be monitored for broadcast NTP packets, make use of the `broadcastclient` command in the `ntp.conf` file.

The `broadcastclient` command takes the following form:

```
broadcastclient
```

Enables the receiving of broadcast messages. Requires authentication by default. See Section 17.6, “Authentication Options for NTP”.

This command configures a system to act as an NTP client. Systems can be both client and server at the same time.

### 17.17.8. Adding a Manycast Server Address

To add a manycast server address, that is to say, to configure an address to allow the clients to discover the server by multicasting NTP packets, make use of the `manycastserver` command in the `ntp.conf` file.

The `manycastserver` command takes the following form:

```
manycastserver address
```

Enables the sending of multicast messages. Where `address` is the address to multicast to. This should be used together with authentication to prevent service disruption.

This command configures a system to act as an NTP server. Systems can be both client and server at the same time.

### 17.17.9. Adding a Multicast Client Address

To add a multicast client address, that is to say, to configure a multicast address to be monitored for multicast NTP packets, make use of the `multicastclient` command in the `ntp.conf` file.

The `multicastclient` command takes the following form:

```
multicastclient address
```
multicastclient address

Enables the receiving of multicast messages. Where address is the address to subscribe to. This should be used together with authentication to prevent service disruption.

This command configures a system to act as an NTP client. Systems can be both client and server at the same time.

17.17.10. Configuring the Burst Option

Using the burst option against a public server is considered abuse. Do not use this option with public NTP servers. Use it only for applications within your own organization.

To increase the average quality of time offset statistics, add the following option to the end of a server command:

burst

At every poll interval, when the server responds, the system will send a burst of up to eight packets instead of the usual one packet. For use with the server command to improve the average quality of the time-offset calculations.

17.17.11. Configuring the iburst Option

To improve the time taken for initial synchronization, add the following option to the end of a server command:

iburst

When the server is unreachable, send a burst of eight packets instead of the usual one packet. The packet spacing is normally 2 s; however, the spacing between the first and second packets can be changed with the calldelay command to allow additional time for a modem or ISDN call to complete. For use with the server command to reduce the time taken for initial synchronization. This is now a default option in the configuration file.

17.17.12. Configuring Symmetric Authentication Using a Key

To configure symmetric authentication using a key, add the following option to the end of a server or peer command:

key number

where number is in the range 1 to 65534 inclusive. This option enables the use of a message authentication code (MAC) in packets. This option is for use with the peer, server, broadcast, and manycastclient commands.

The option can be used in the /etc/ntp.conf file as follows:

server 192.168.1.1 key 10
broadcast 192.168.1.255 key 20
manycastclient 239.255.254.254 key 30
See also Section 17.6, “Authentication Options for NTP”.

17.17.13. Configuring the Poll Interval

To change the default poll interval, add the following options to the end of a server or peer command:

```
minpoll value and maxpoll value
```

Options to change the default poll interval, where the interval in seconds will be calculated by raising 2 to the power of value, in other words, the interval is expressed in \( \log_2 \) seconds. The default minpoll value is 6, \( 2^6 \) equates to 64 s. The default value for maxpoll is 10, which equates to 1024 s. Allowed values are in the range 3 to 17 inclusive, which equates to 8 s to 36.4 h respectively. These options are for use with the peer or server. Setting a shorter maxpoll may improve clock accuracy.

To specify that a particular server should be preferred above others of similar statistical quality, add the following option to the end of a server or peer command:

```
prefer
```

Use this server for synchronization in preference to other servers of similar statistical quality. This option is for use with the peer or server commands.

17.17.15. Configuring the Time-to-Live for NTP Packets

To specify that a particular time-to-live (TTL) value should be used in place of the default, add the following option to the end of a server or peer command:

```
ttl value
```

Specify the time-to-live value to be used in packets sent by broadcast servers and multicast NTP servers. Specify the maximum time-to-live value to use for the “expanding ring search” by a manycast client. The default value is 127.

17.17.16. Configuring the NTP Version to Use

To specify that a particular version of NTP should be used in place of the default, add the following option to the end of a server or peer command:

```
version value
```

Specify the version of NTP set in created NTP packets. The value can be in the range 1 to 4. The default is 4.

17.18. CONFIGURING THE HARDWARE CLOCK UPDATE

The system clock can be used to update the hardware clock, also known as the real-time clock (RTC). This section shows three approaches to the task:

- Instant one-time update
To perform an instant one-time update of the hardware clock, run this command as root:

```
~$ hwclock --systohc
```

**Update on every boot**

To make the hardware clock update on every boot after executing the `ntpdate` synchronization utility, do the following:

1. Add the following line to the `/etc/sysconfig/ntpdate` file:
   
   ```
   SYNC_HWCLOCK=yes
   ```
2. Enable the `ntpdate` service as root:
   
   ```
   ~$ systemctl enable ntpdate.service
   ```

Note that the `ntpdate` service uses the NTP servers defined in the `/etc/ntp/step-tickers` file.

**NOTE**

On virtual machines, the hardware clock will be updated on the next boot of the host machine, not of the virtual machine.

**Update via NTP**

You can make the hardware clock update every time the system clock is updated by the `ntpd` or `chronyd` service:

Start the `ntpd` service as root:

```
~$ systemctl start ntpd.service
```

To make the behavior persistent across boots, make the service start automatically at the boot time:

```
~$ systemctl enable ntpd.service
```

or

Start the `chronyd` service as root:

```
~$ systemctl start chronyd.service
```

To make the behavior persistent across boots, make the service start automatically at the boot time:

```
~$ systemctl enable chronyd.service
```

As a result, every time the system clock is synchronized by `ntpd` or `chronyd`, the kernel automatically updates the hardware clock in 11 minutes.
To check the synchronization of the software clock with the hardware clock, use the `ntpd` `-c kerninfo` or the `ntptime` command as root:

```
~]# ntpdc -c kerninfo
```

The result may look like this:

```
pll offset:           0 s
pll frequency:        0.000 ppm
maximum error:        8.0185 s
estimated error:      0 s
status: 2001 pll nano
pll time constant:    6
precision:            1e-09 s
frequency tolerance:  500 ppm
```

or

```
~]# ntptime
```

The result may look like this:

```
ntp_gettime() returns code 0 (OK)
  time dcb5798.c3de2e0  Mon, May 8 2017 11:34:00.765, (.765135199),
  maximum error 8010000 us, estimated error 0 us, TAI offset 0
ntp_adjtime() returns code 0 (OK)
  modes 0x0 (),
  offset 0.000 us, frequency 0.000 ppm, interval 1 s,
  maximum error 8010000 us, estimated error 0 us,
  status 0x2001 (PLL,NANO),
  time constant 6, precision 0.001 us, tolerance 500 ppm,
```

To recognize whether the software clock is synchronized with the hardware clock, see the `status` line in the output (highlighted).

If the third digit from the end is 4, the software clock is not synchronized with the hardware clock.

```
status 0x2401
```
If the second digit of the last four digits is not 4, the software clock is synchronized with the hardware clock.

```
status 0x2001
```

### 17.19. CONFIGURING CLOCK SOURCES

To list the available clock sources on your system, issue the following commands:

```
~]$ cd /sys/devices/system/clocksource/clocksource0/
clocksource0]$ cat available_clocksource
kvm-clock tsc hpet acpi_pm
clocksource0]$ cat current_clocksource
kvm-clock
```

In the above example, the kernel is using *kvm-clock*. This was selected at boot time as this is a virtual machine. Note that the available clock source is architecture dependent.

To override the default clock source, append the `clocksource` directive to the end of the kernel's GRUB menu entry. Use the `grubby` tool to make the change. For example, to force the default kernel on a system to use the `tsc` clock source, enter a command as follows:

```
~]# grubby --args=clocksource=tsc --update-kernel=DEFAULT
```

The `--update-kernel` parameter also accepts the keyword `ALL`, or a comma separated list of kernel index numbers.

See Chapter 25, *Working with GRUB 2* for more information on making changes to the GRUB menu.

### 17.20. ADDITIONAL RESOURCES

The following sources of information provide additional resources regarding *NTP* and *ntpd*.

#### 17.20.1. Installed Documentation

- **ntpd(8)** man page — Describes *ntpd* in detail, including the command-line options.
- **ntp.conf(5)** man page — Contains information on how to configure associations with servers and peers.
- **ntpq(8)** man page — Describes the *NTP* query utility for monitoring and querying an *NTP* server.
- **ntpd(8)** man page — Describes the *ntpd* utility for querying and changing the state of *ntpd*.
- **ntp_auth(5)** man page — Describes authentication options, commands, and key management for *ntpd*.
- **ntp_keygen(8)** man page — Describes generating public and private keys for *ntpd*.
- **ntp_acc(5)** man page — Describes access control options using the `restrict` command.
- **ntp_mon(5)** man page – Describes monitoring options for the gathering of statistics.
- **ntp_clock(5)** man page – Describes commands for configuring reference clocks.
- **ntp_misc(5)** man page – Describes miscellaneous options.
- **ntp_decode(5)** man page – Lists the status words, event messages and error codes used for `ntpd` reporting and monitoring.
- **ntpstat(8)** man page – Describes a utility for reporting the synchronization state of the NTP daemon running on the local machine.
- **ntptime(8)** man page – Describes a utility for reading and setting kernel time variables.
- **tickadj(8)** man page – Describes a utility for reading, and optionally setting, the length of the tick.

CHAPTER 18. CONFIGURING PTP USING PTP4L

18.1. INTRODUCTION TO PTP

The Precision Time Protocol (PTP) is a protocol used to synchronize clocks in a network. When used in conjunction with hardware support, PTP is capable of sub-microsecond accuracy, which is far better than is normally obtainable with NTP. PTP support is divided between the kernel and user space. The kernel in Red Hat Enterprise Linux includes support for PTP clocks, which are provided by network drivers. The actual implementation of the protocol is known as linuxptp, a PTPv2 implementation according to the IEEE standard 1588 for Linux.

The linuxptp package includes the ptp4l and phc2sys programs for clock synchronization. The ptp4l program implements the PTP boundary clock and ordinary clock. With hardware time stamping, it is used to synchronize the PTP hardware clock to the master clock, and with software time stamping it synchronizes the system clock to the master clock. The phc2sys program is needed only with hardware time stamping, for synchronizing the system clock to the PTP hardware clock on the network interface card (NIC).

18.1.1. Understanding PTP

The clocks synchronized by PTP are organized in a master-slave hierarchy. The slaves are synchronized to their masters which may be slaves to their own masters. The hierarchy is created and updated automatically by the best master clock (BMC) algorithm, which runs on every clock. When a clock has only one port, it can be master or slave, such a clock is called an ordinary clock (OC). A clock with multiple ports can be master on one port and slave on another, such a clock is called a boundary clock (BC). The top-level master is called the grandmaster clock, which can be synchronized by using a Global Positioning System (GPS) time source. By using a GPS-based time source, disparate networks can be synchronized with a high-degree of accuracy.
18.1.2. Advantages of PTP

One of the main advantages that PTP has over the Network Time Protocol (NTP) is hardware support present in various network interface controllers (NIC) and network switches. This specialized hardware allows PTP to account for delays in message transfer, and greatly improves the accuracy of time synchronization. While it is possible to use non-PTP enabled hardware components within the network, this will often cause an increase in jitter or introduce an asymmetry in the delay resulting in synchronization inaccuracies, which add up with multiple non-PTP aware components used in the communication path. To achieve the best possible accuracy, it is recommended that all networking components between PTP clocks are PTP hardware enabled. Time synchronization in larger networks where not all of the networking hardware supports PTP might be better suited for NTP.

With hardware PTP support, the NIC has its own on-board clock, which is used to time stamp the received and transmitted PTP messages. It is this on-board clock that is synchronized to the PTP master, and the computer's system clock is synchronized to the PTP hardware clock on the NIC. With software PTP support, the system clock is used to time stamp the PTP messages and it is synchronized to the PTP master directly. Hardware PTP support provides better accuracy since the NIC can time stamp the PTP packets at the exact moment they are sent and received while software PTP support
requires additional processing of the PTP packets by the operating system.

18.2. USING PTP

In order to use PTP, the kernel network driver for the intended interface has to support either software or hardware time stamping capabilities.

18.2.1. Checking for Driver and Hardware Support

In addition to hardware time stamping support being present in the driver, the NIC must also be capable of supporting this functionality in the physical hardware. The best way to verify the time stamping capabilities of a particular driver and NIC is to use the `ethtool` utility to query the interface as follows:

```
~
]# ethtool -T eth3
Time stamping parameters for eth3:
Capabilities:
hardware-transmit (SOF_TIMESTAMPING_TX_HARDWARE)
software-transmit (SOF_TIMESTAMPING_TX_SOFTWARE)
hardware-receive (SOF_TIMESTAMPING_RX_HARDWARE)
software-receive (SOF_TIMESTAMPING_RX_SOFTWARE)
software-system-clock (SOF_TIMESTAMPING_SOFTWARE)
hardware-raw-clock (SOF_TIMESTAMPING_RAW_HARDWARE)
PTP Hardware Clock: 0
Hardware Transmit Timestamp Modes:
off (HWTSTAMP_TX_OFF)
on (HWTSTAMP_TX_ON)
Hardware Receive Filter Modes:
none (HWTSTAMP_FILTER_NONE)
all (HWTSTAMP_FILTER_ALL)
```

Where `eth3` is the interface you want to check.

For software time stamping support, the parameters list should include:

- SOF_TIMESTAMPING_SOFTWARE
- SOF_TIMESTAMPING_TX_SOFTWARE
- SOF_TIMESTAMPING_RX_SOFTWARE

For hardware time stamping support, the parameters list should include:

- SOF_TIMESTAMPING_RAW_HARDWARE
- SOF_TIMESTAMPING_TX_HARDWARE
- SOF_TIMESTAMPING_RX_HARDWARE

18.2.2. Installing PTP

The kernel in Red Hat Enterprise Linux includes support for PTP. User space support is provided by the tools in the `linuxptp` package. To install `linuxptp`, issue the following command as `root`:

```
~
]# yum install linuxptp
```
This will install `ptp4l` and `phc2sys`.

Do not run more than one service to set the system clock's time at the same time. If you intend to serve PTP time using NTP, see Section 18.8, “Serving PTP Time with NTP”.

### 18.2.3. Starting `ptp4l`

The `ptp4l` program can be started from the command line or it can be started as a service. When running as a service, options are specified in the `/etc/sysconfig/ptp4l` file. Options required for use both by the service and on the command line should be specified in the `/etc/ptp4l.conf` file. The `/etc/sysconfig/ptp4l` file includes the `-f /etc/ptp4l.conf` command line option, which causes the `ptp4l` program to read the `/etc/ptp4l.conf` file and process the options it contains. The use of the `/etc/ptp4l.conf` is explained in Section 18.4, “Specifying a Configuration File”. More information on the different `ptp4l` options and the configuration file settings can be found in the `ptp4l(8)` man page.

**Starting `ptp4l` as a Service**

To start `ptp4l` as a service, issue the following command as `root`:

```bash
[~]# systemctl start ptp4l
```

For more information on managing system services in Red Hat Enterprise Linux 7, see Chapter 9, *Managing Services with systemd*.

**Using `ptp4l` From The Command Line**

The `ptp4l` program tries to use hardware time stamping by default. To use `ptp4l` with hardware time stamping capable drivers and NICs, you must provide the network interface to use with the `-i` option. Enter the following command as `root`:

```bash
[~]# ptp4l -i eth3 -m
```

Where `eth3` is the interface you want to configure. Below is example output from `ptp4l` when the PTP clock on the NIC is synchronized to a master:

```bash
[~]# ptp4l -i eth3 -m
selected eth3 as PTP clock
port 1: INITIALIZING to LISTENING on INITIALIZE
port 0: INITIALIZING to LISTENING on INITIALIZE
port 1: new foreign master 00a069.fffe.0b552d-1
selected best master clock 00a069.fffe.0b552d
port 1: LISTENING to UNCALIBRATED on RS_SLAVE
master offset -23947 s0 freq +0 path delay       11350
master offset -28867 s0 freq +0 path delay       11236
master offset -32801 s0 freq +0 path delay       10841
master offset -37203 s1 freq +0 path delay       10583
master offset  -7275 s2 freq -30575 path delay   10583
port 1: UNCALIBRATED to SLAVE on MASTER_CLOCK_SELECTED
master offset  -4552 s2 freq -30035 path delay   10385
```

The master offset value is the measured offset from the master in nanoseconds. The s0, s1, s2 strings indicate the different clock servo states: s0 is unlocked, s1 is clock step and s2 is locked. Once the servo is in the locked state (s2), the clock will not be stepped (only slowly adjusted) unless the `pi_offset_const` option is set to a positive value in the configuration file (described in the...
The adj value is the frequency adjustment of the clock in parts per billion (ppb). The path delay value is the estimated delay of the synchronization messages sent from the master in nanoseconds. Port 0 is a Unix domain socket used for local PTP management. Port 1 is the `eth3` interface (based on the example above.) INITIALIZING, LISTENING, UNCALIBRATED and SLAVE are some of possible port states which change on the INITIALIZE, RS_SLAVE, MASTER_CLOCK_SELECTED events. In the last state change message, the port state changed from UNCALIBRATED to SLAVE indicating successful synchronization with a PTP master clock.

Logging Messages From ptp4l
By default, messages are sent to `/var/log/messages`. However, specifying the `–m` option enables logging to standard output which can be useful for debugging purposes.

To enable software time stamping, the `–S` option needs to be used as follows:

```
~]# ptp4l -i eth3 -m -S
```

18.2.3.1. Selecting a Delay Measurement Mechanism
There are two different delay measurement mechanisms and they can be selected by means of an option added to the ptp4l command as follows:

`-P`

The `-P` selects the peer-to-peer (P2P) delay measurement mechanism.

The P2P mechanism is preferred as it reacts to changes in the network topology faster, and may be more accurate in measuring the delay, than other mechanisms. The P2P mechanism can only be used in topologies where each port exchanges PTP messages with at most one other P2P port. It must be supported and used by all hardware, including transparent clocks, on the communication path.

`-E`

The `-E` selects the end-to-end (E2E) delay measurement mechanism. This is the default.

The E2E mechanism is also referred to as the delay “request-response” mechanism.

`-A`

The `-A` enables automatic selection of the delay measurement mechanism.

The automatic option starts ptp4l in E2E mode. It will change to P2P mode if a peer delay request is received.

NOTE

All clocks on a single PTP communication path must use the same mechanism to measure the delay. Warnings will be printed in the following circumstances:

- When a peer delay request is received on a port using the E2E mechanism.
- When a E2E delay request is received on a port using the P2P mechanism.

18.3. USING PTP WITH MULTIPLE INTERFACES
When using PTP with multiple interfaces in different networks, it is necessary to change the reverse path forwarding mode to loose mode. Red Hat Enterprise Linux 7 defaults to using Strict Reverse Path Forwarding following the Strict Reverse Path recommendation from RFC 3704, Ingress Filtering for Multihomed Networks. See the Reverse Path Forwarding section in the Red Hat Enterprise Linux 7 Security Guide for more details.

The `sysctl` utility is used to read and write values to tunables in the kernel. Changes to a running system can be made using `sysctl` commands directly on the command line and permanent changes can be made by adding lines to the `/etc/sysctl.conf` file.

- To change to loose mode filtering globally, enter the following commands as root:
  ```shell
  ~]# sysctl -w net.ipv4.conf.default.rp_filter=2
  ~]# sysctl -w net.ipv4.conf.all.rp_filter=2
  ```

- To change the reverse path filtering mode per network interface, use the `net.ipv4.interface.rp_filter` command on all PTP interfaces. For example, for an interface with device name `em1`:
  ```shell
  ~]# sysctl -w net.ipv4.conf.em1.rp_filter=2
  ```

To make these settings persistent across reboots, modify the `/etc/sysctl.conf` file. You can change the mode for all interfaces, or for a particular interface.

To change the mode for all interfaces, open the `/etc/sysctl.conf` file with an editor running as the root user and add a line as follows:

```plaintext
net.ipv4.conf.all.rp_filter=2
```

To change only certain interfaces, add multiple lines in the following format:

```plaintext
net.ipv4.conf.interface.rp_filter=2
```

**NOTE**

When using the settings for all and particular interfaces as well, maximum value from `conf/{all,interface}/rp_filter` is used when doing source validation on each interface.

You can also change the mode by using the `default` setting, which means that it applies only to the newly created interfaces.

For more information on using the `all`, `default`, or a specific device settings in the `sysctl` parameters, see the Red Hat Knowledgebase article What is the difference between "all", "default" and a specific device in a sysctl parameter?.

Note that you might experience issues of two types due to the timing of the `sysctl` service run during the boot process:

1. Drivers are loaded before the `sysctl` service runs.
   
   In this case, affected network interfaces use the mode preset from the kernel, and `sysctl` defaults are ignored.
For solution of this problem, see the Red Hat Knowledgebase article What is the difference between "all", "default" and a specific device in a sysctl parameter?.

2. Drivers are loaded or reloaded after the sysctl service runs.

In this case, it is possible that some sysctl.conf parameters are not used after reboot. These settings may not be available or they may return to defaults.

For solution of this problem, see the Red Hat Knowledgebase article Some sysctl.conf parameters are not used after reboot, manually adjusting the settings works as expected.

18.4. SPECIFYING A CONFIGURATION FILE

The command line options and other options, which cannot be set on the command line, can be set in an optional configuration file.

No configuration file is read by default, so it needs to be specified at runtime with the -f option. For example:

~]# ptp4l -f /etc/ptp4l.conf

A configuration file equivalent to the -i eth3 -m -S options shown above would look as follows:

~]# cat /etc/ptp4l.conf
[global]
verbose               1
time_stamping         software
[eth3]

18.5. USING THE PTP MANAGEMENT CLIENT

The PTP management client, pmc, can be used to obtain additional information from ptp4l as follows:

~]# pmc -u -b 0 'GET CURRENT_DATA_SET'
sending: GET CURRENT_DATA_SET
    90e2ba.fffe.20c7f8-0 seq 0 RESPONSE MANAGEMENT CURRENT_DATA_SET
    stepsRemoved 1
    offsetFromMaster -142.0
    meanPathDelay 9310.0

~]# pmc -u -b 0 'GET TIME_STATUS_NP'
sending: GET TIME_STATUS_NP
    90e2ba.fffe.20c7f8-0 seq 0 RESPONSE MANAGEMENT TIME_STATUS_NP
    master_offset 310
    ingress_time 1361545089345029441
    cumulativeScaledRateOffset +1.0000000000
    scaledLastGmPhaseChange 0
    gmTimeBaseIndicator 0
    lastGmPhaseChange 0x00000000000000000000000000000000
    gmPresent true
    gmIdentity 00a069.fffe.0b552d

348
Setting the -b option to zero limits the boundary to the locally running \texttt{ptp4l} instance. A larger boundary value will retrieve the information also from PTP nodes further from the local clock. The retrievable information includes:

- \texttt{stepsRemoved} is the number of communication paths to the grandmaster clock.
- \texttt{offsetFromMaster} and master\_offset is the last measured offset of the clock from the master in nanoseconds.
- \texttt{meanPathDelay} is the estimated delay of the synchronization messages sent from the master in nanoseconds.
- if \texttt{gmPresent} is true, the PTP clock is synchronized to a master, the local clock is not the grandmaster clock.
- \texttt{gmIdentity} is the grandmaster’s identity.

For a full list of pmc commands, type the following as root:

```
~]# pmc help
```

Additional information is available in the \texttt{pmc(8)} man page.

\section*{18.6. SYNCHRONIZING THE CLOCKS}

The \texttt{phc2sys} program is used to synchronize the system clock to the PTP hardware clock (PHC) on the NIC. The \texttt{phc2sys} service is configured in the \texttt{/etc/sysconfig/phc2sys} configuration file. The default setting in the \texttt{/etc/sysconfig/phc2sys} file is as follows:

```
OPTIONS="-a -r"
```

The -a option causes \texttt{phc2sys} to read the clocks to be synchronized from the \texttt{ptp4l} application. It will follow changes in the PTP port states, adjusting the synchronization between the NIC hardware clocks accordingly. The system clock is not synchronized, unless the -r option is also specified. If you want the system clock to be eligible to become a time source, specify the -r option twice.

After making changes to \texttt{/etc/sysconfig/phc2sys}, restart the \texttt{phc2sys} service from the command line by issuing a command as root:

```
~]# systemctl restart phc2sys
```

Under normal circumstances, use \texttt{systemctl} commands to start, stop, and restart the \texttt{phc2sys} service.

When you do not want to start \texttt{phc2sys} as a service, you can start it from the command line. For example, enter the following command as root:

```
~]# phc2sys -a -r
```

The -a option causes \texttt{phc2sys} to read the clocks to be synchronized from the \texttt{ptp4l} application. If you want the system clock to be eligible to become a time source, specify the -r option twice.

Alternately, use the -s option to synchronize the system clock to a specific interface’s PTP hardware clock. For example:
The `-w` option waits for the running `ptp4l` application to synchronize the PTP clock and then retrieves the TAI to UTC offset from `ptp4l`.

Normally, PTP operates in the *International Atomic Time* (TAI) timescale, while the system clock is kept in *Coordinated Universal Time* (UTC). The current offset between the TAI and UTC timescales is 36 seconds. The offset changes when leap seconds are inserted or deleted, which typically happens every few years. The `-O` option needs to be used to set this offset manually when the `-w` is not used, as follows:

```
-]# phc2sys -s eth3 -O -36
```

Once the `phc2sys` servo is in a locked state, the clock will not be stepped, unless the `-S` option is used. This means that the `phc2sys` program should be started after the `ptp4l` program has synchronized the PTP hardware clock. However, with `-w`, it is not necessary to start `phc2sys` after `ptp4l` as it will wait for it to synchronize the clock.

The `phc2sys` program can also be started as a service by running:

```
-]# systemctl start phc2sys
```

When running as a service, options are specified in the `/etc/sysconfig/phc2sys` file. More information on the different `phc2sys` options can be found in the `phc2sys(8)` man page.

Note that the examples in this section assume the command is run on a slave system or slave port.

### 18.7. VERIFYING TIME SYNCHRONIZATION

When PTP time synchronization is working correctly, new messages with offsets and frequency adjustments are printed periodically to the `ptp4l` and `phc2sys` outputs if hardware time stamping is used. The output values converge shortly. You can see these messages in the `/var/log/messages` file.

The following examples of the `ptp4l` and the `phc2sys` output contain:

- offset (in nanoseconds)
- frequency offset (in parts per billion (ppb))
- path delay (in nanoseconds)

Example of the `ptp4l` output:

```
ptp4l[352.359]: selected /dev/ptp0 as PTP clock
ptp4l[352.361]: port 1: INITIALIZING to LISTENING on INITIALIZE
ptp4l[352.361]: port 0: INITIALIZING to LISTENING on INITIALIZE
ptp4l[353.210]: port 1: new foreign master 00a069.fffe.0b552d-1
ptp4l[357.214]: selected best master clock 00a069.fffe.0b552d
ptp4l[357.214]: port 1: LISTENING to UNCALIBRATED on RS_SLAVE
ptp4l[359.224]: master offset       3304 s0 freq      +0 path delay 9202
ptp4l[360.224]: master offset       3708 s1 freq  -29492 path delay 9202
```
Example of the **phc2sys** output:

```
phc2sys[526.527]: Waiting for ptp4l...
phc2sys[527.528]: Waiting for ptp4l...
phc2sys[528.528]: phc offset     55341 s0 freq      +0 delay   2729
phc2sys[529.528]: phc offset     54658 s1 freq  -37690 delay   2725
phc2sys[530.528]: phc offset     888 s2 freq  -36802 delay   2756
phc2sys[531.528]: phc offset    1156 s2 freq  -36268 delay   2766
phc2sys[532.528]: phc offset    411 s2 freq  -36666 delay   2738
phc2sys[533.528]: phc offset    73 s2 freq  -37026 delay   2764
phc2sys[534.528]: phc offset     39 s2 freq  -36936 delay   2746
phc2sys[535.528]: phc offset     95 s2 freq  -36869 delay   2733
phc2sys[536.528]: phc offset    -359 s2 freq  -37294 delay   2738
phc2sys[537.528]: phc offset   -257 s2 freq  -37300 delay   2753
phc2sys[538.528]: phc offset    119 s2 freq  -37001 delay   2745
phc2sys[539.528]: phc offset    288 s2 freq  -36796 delay   2766
phc2sys[540.529]: phc offset   -149 s2 freq  -37147 delay   2760
phc2sys[541.529]: phc offset   -352 s2 freq  -37395 delay   2771
phc2sys[542.529]: phc offset    166 s2 freq  -36982 delay   2748
phc2sys[543.529]: phc offset     50 s2 freq  -37048 delay   2756
phc2sys[544.530]: phc offset    -31 s2 freq  -37114 delay   2748
phc2sys[545.530]: phc offset   -333 s2 freq  -37426 delay   2747
phc2sys[546.530]: phc offset    194 s2 freq  -36999 delay   2749
```

To reduce the **ptp4l** output and print only the values, use the `summary_interval` directive. The `summary_interval` directive is specified as $2^n$ in seconds. For example, to reduce the output to every 1024 seconds, add the following line to the `/etc/ptp4l.conf` file:

```
summary_interval 10
```
An example of the `ptp4l` output, with `summary_interval` set to 6:

```
ptp4l: [615.253] selected /dev/ptp0 as PTP clock
ptp4l: [615.255] port 1: INITIALIZING to LISTENING on INITIALIZE
ptp4l: [615.255] port 0: INITIALIZING to LISTENING on INITIALIZE
ptp4l: [615.564] port 1: new foreign master 00a069.fffe.0b552d-1
ptp4l: [619.574] selected best master clock 00a069.fffe.0b552d
ptp4l: [619.574] port 1: LISTENING to UNCALIBRATED on RS_SLAVE
ptp4l: [623.573] port 1: UNCALIBRATED to SLAVE on MASTER_CLOCK_SELECTED
ptp4l: [684.649] rms  669 max 3691 freq -29383 ± 3735 delay  9232 ± 122
ptp4l: [748.724] rms  253 max  588 freq -29787 ± 221 delay  9219 ± 158
ptp4l: [812.793] rms  287 max  673 freq -29802 ± 248 delay  9211 ± 183
ptp4l: [876.853] rms  226 max  534 freq -29795 ± 197 delay  9221 ± 138
ptp4l: [940.925] rms  250 max  562 freq -29801 ± 218 delay  9199 ± 148
ptp4l: [1004.988] rms  226 max  525 freq -29802 ± 196 delay  9228 ± 143
ptp4l: [1069.065] rms  244 max  688 freq -29790 ± 211 delay  9201 ± 162
```

By default, `summary_interval` is set to 0, so messages are printed once per second, which is the maximum frequency. The messages are logged at the LOG_INFO level. To disable messages, use the `-1` option to set the maximum log level to 5 or lower:

```
~]# phc2sys -l 5
```

You can use the `-u` option to reduce the `phc2sys` output:

```
~]# phc2sys -u summary-updates
```

Where `summary-updates` is the number of clock updates to include in summary statistics. An example follows:

```
~]# phc2sys -s eth3 -w -m -u 60
phc2sys[700.948]: rms 1837 max 10123 freq -36474 ± 4752 delay 2752 ± 16
phc2sys[760.954]: rms 194 max  457 freq -37084 ± 174 delay 2753 ± 12
phc2sys[820.963]: rms 211 max  487 freq -37085 ± 185 delay 2750 ± 19
phc2sys[880.968]: rms 183 max  440 freq -37102 ± 164 delay 2734 ± 91
phc2sys[940.973]: rms 244 max  584 freq -37095 ± 216 delay 2748 ± 16
phc2sys[1000.979]: rms 220 max  573 freq -36666 ± 182 delay 2747 ± 43
phc2sys[1060.984]: rms 266 max  675 freq -36759 ± 234 delay 2753 ± 17
```

When used with these options, the interval for updating the statistics is set to 60 seconds (`-u`), `phc2sys` waits until `ptp4l` is in synchronized state (`-w`), and messages are printed to the standard output (`-m`). For further details about the `phc2sys` options, see the `phc2sys(5)` man page.

The output includes:

- offset root mean square (rms)
- maximum absolute offset (max)
- frequency offset (freq): its mean, and standard deviation
- path delay (delay): its mean, and standard deviation
18.8. SERVING PTP TIME WITH NTP

The ntpd daemon can be configured to distribute the time from the system clock synchronized by ptp4l or phc2sys by using the LOCAL reference clock driver. To prevent ntpd from adjusting the system clock, the ntp.conf file must not specify any NTP servers. The following is a minimal example of ntp.conf:

```
[global]
server 127.127.1.0
fudge 127.127.1.0 stratum 0
```

NOTE

When the DHCP client program, dhclient, receives a list of NTP servers from the DHCP server, it adds them to ntp.conf and restarts the service. To disable that feature, add PEERNTP=no to /etc/sysconfig/network.

18.9. SERVING NTP TIME WITH PTP

NTP to PTP synchronization in the opposite direction is also possible. When ntpd is used to synchronize the system clock, ptp4l can be configured with the priority1 option (or other clock options included in the best master clock algorithm) to be the grandmaster clock and distribute the time from the system clock via PTP:

```
[global]
priority1 127
```

With hardware time stamping, phc2sys needs to be used to synchronize the PTP hardware clock to the system clock. If running phc2sys as a service, edit the /etc/sysconfig/phc2sys configuration file. The default setting in the /etc/sysconfig/phc2sys file is as follows:

```
OPTIONS="-a -r"
```

As root, edit that line as follows:

```
[global]
```

OPTIONS="-a -r -r"

The -r option is used twice here to allow synchronization of the PTP hardware clock on the NIC from the system clock. Restart the phc2sys service for the changes to take effect:

```
# systemctl restart phc2sys
```

To prevent quick changes in the PTP clock's frequency, the synchronization to the system clock can be loosened by using smaller P (proportional) and I (integral) constants for the PI servo:

```
# phc2sys -a -r -r -P 0.01 -I 0.0001
```
18.10. SYNCHRONIZE TO PTP OR NTP TIME USING TIMEMASTER

When there are multiple PTP domains available on the network, or fallback to NTP is needed, the timemaster program can be used to synchronize the system clock to all available time sources. The PTP time is provided by phc2sys and ptp4l via shared memory driver (SHM reference clocks to chronyd or ntpd (depending on the NTP daemon that has been configured on the system). The NTP daemon can then compare all time sources, both PTP and NTP, and use the best sources to synchronize the system clock.

On start, timemaster reads a configuration file that specifies the NTP and PTP time sources, checks which network interfaces have their own or share a PTP hardware clock (PHC), generates configuration files for ptp4l and chronyd or ntpd, and starts the ptp4l, phc2sys, and chronyd or ntpd processes as needed. It will remove the generated configuration files on exit. It writes configuration files for chronyd, ntpd, and ptp4l to /var/run/timemaster/.

18.10.1. Starting timemaster as a Service

To start timemaster as a service, issue the following command as root:

~]# systemctl start timemaster

This will read the options in /etc/timemaster.conf. For more information on managing system services in Red Hat Enterprise Linux 7, see Chapter 9, Managing Services with systemd.

18.10.2. Understanding the timemaster Configuration File

Red Hat Enterprise Linux provides a default /etc/timemaster.conf file with a number of sections containing default options. The section headings are enclosed in brackets.

To view the default configuration, issue a command as follows:

~]$ less /etc/timemaster.conf
# Configuration file for timemaster

#[ntp_server ntp-server.local]
#minpoll 4
#maxpoll 4

#[ptp_domain 0]
#interfaces eth0

[timemaster]
ntp_program chronyd

[chrony.conf]
include /etc/chrony.conf

[ntp.conf]
includelfile /etc/ntp.conf

[ptp4l.conf]
[chrony]
path /usr/sbin/chronyd
options -u chrony

[ntpd]
path /usr/sbin/ntpd
options -u ntp:ntp -g

[phc2sys]
path /usr/sbin/phc2sys

[ptp4l]
path /usr/sbin/ptp4l

Notice the section named as follows:

[ntp_server address]

This is an example of an NTP server section, “ntp-server.local” is an example of a host name for an NTP server on the local LAN. Add more sections as required using a host name or IP address as part of the section name. Note that the short polling values in that example section are not suitable for a public server, see Chapter 17, Configuring NTP Using ntpd for an explanation of suitable minpoll and maxpoll values.

Notice the section named as follows:

[ptp_domain number]

A “PTP domain” is a group of one or more PTP clocks that synchronize to each other. They may or may not be synchronized to clocks in another domain. Clocks that are configured with the same domain number make up the domain. This includes a PTP grandmaster clock. The domain number in each “PTP domain” section needs to correspond to one of the PTP domains configured on the network.

An instance of ptp4l is started for every interface which has its own PTP clock and hardware time stamping is enabled automatically. Interfaces that support hardware time stamping have a PTP clock (PHC) attached, however it is possible for a group of interfaces on a NIC to share a PHC. A separate ptp4l instance will be started for each group of interfaces sharing the same PHC and for each interface that supports only software time stamping. All ptp4l instances are configured to run as a slave. If an interface with hardware time stamping is specified in more than one PTP domain, then only the first ptp4l instance created will have hardware time stamping enabled.

Notice the section named as follows:

[timemaster]

The default timemaster configuration includes the system ntpd and chrony configuration (/etc/ntp.conf or /etc/chronyd.conf) in order to include the configuration of access restrictions and authentication keys. That means any NTP servers specified there will be used with timemaster too.

The section headings are as follows:

- [ntp_server ntp-server.local] – Specify polling intervals for this server. Create additional sections as required. Include the host name or IP address in the section heading.
18.10.3. Configuring timemaster Options

Procedure 18.1. Editing the timemaster Configuration File

1. To change the default configuration, open the /etc/timemaster.conf file for editing as root:

   ```
   ~]\# vi /etc/timemaster.conf
   ```

2. For each NTP server you want to control using timemaster, create [ntp_server address] sections. Note that the short polling values in the example section are not suitable for a public server, see Chapter 17, Configuring NTP Using ntpd for an explanation of suitable minpoll and maxpoll values.

3. To add interfaces that should be used in a domain, edit the #[ptp_domain 0] section and add the interfaces. Create additional domains as required. For example:

   ```
   [ptp_domain 0]
   interfaces eth0
   
   [ptp_domain 1]
   interfaces eth1
   ```

4. If required to use ntpd as the NTP daemon on this system, change the default entry in the [timemaster] section from chronyd to ntpd. See Chapter 16, Configuring NTP Using the chrony Suite for information on the differences between ntpd and chronyd.

5. If using chronyd as the NTP server on this system, add any additional options below the default include /etc/chrony.conf entry in the [chrony.conf] section. Edit the default include entry if the path to /etc/chrony.conf is known to have changed.
6. If using ntpd as the NTP server on this system, add any additional options below the default `include /etc/ntp.conf` entry in the `[ntpd.conf]` section. Edit the default `include` entry if the path to `/etc/ntp.conf` is known to have changed.

7. In the `[ptp4l.conf]` section, add any options to be copied to the configuration file generated for ptp4l. This chapter documents common options and more information is available in the `ptp4l(8)` manual page.

8. In the `[chronyd]` section, add any command line options to be passed to `chronyd` when called by timemaster. See Chapter 16, Configuring NTP Using the chrony Suite for information on using chronyd.

9. In the `[ntpd]` section, add any command line options to be passed to `ntpd` when called by timemaster. See Chapter 17, Configuring NTP Using ntpd for information on using `ntpd`.

10. In the `[phc2sys]` section, add any command line options to be passed to `phc2sys` when called by timemaster. This chapter documents common options and more information is available in the `phy2sys(8)` manual page.

11. In the `[ptp4l]` section, add any command line options to be passed to `ptp4l` when called by timemaster. This chapter documents common options and more information is available in the `ptp4l(8)` manual page.

12. Save the configuration file and restart timemaster by issuing the following command as `root`:

```bash
~]# systemctl restart timemaster
```

### 18.11. IMPROVING ACCURACY

Previously, test results indicated that disabling the tickless kernel capability could significantly improve the stability of the system clock, and thus improve the PTP synchronization accuracy (at the cost of increased power consumption). The kernel tickless mode can be disabled by adding `nohz=off` to the kernel boot option parameters. However, recent improvements applied to `kernel-3.10.0-197.el7` have greatly improved the stability of the system clock and the difference in stability of the clock with and without `nohz=off` should be much smaller now for most users.

The ptp4l and phc2sys applications can be configured to use a new adaptive servo. The advantage over the PI servo is that it does not require configuration of the PI constants to perform well. To make use of this for ptp4l, add the following line to the `/etc/ptp4l.conf` file:

```plaintext
clock_servo linreg
```

After making changes to `/etc/ptp4l.conf`, restart the `ptp4l` service from the command line by issuing the following command as `root`:

```bash
~]# systemctl restart ptp4l
```

To make use of this for phc2sys, add the following line to the `/etc/sysconfig/phc2sys` file:

```plaintext
- E linreg
```

After making changes to `/etc/sysconfig/phc2sys`, restart the `phc2sys` service from the command line by issuing the following command as `root`:
18.12. ADDITIONAL RESOURCES

The following sources of information provide additional resources regarding PTP and the ptp4l tools.

18.12.1. Installed Documentation

- **ptp4l(8) man page** – Describes ptp4l options including the format of the configuration file.
- **pmc(8) man page** – Describes the PTP management client and its command options.
- **phc2sys(8) man page** – Describes a tool for synchronizing the system clock to a PTP hardware clock (PHC).
- **timemaster(8) man page** – Describes a program that uses ptp4l and phc2sys to synchronize the system clock using chronyd or ntpd.

18.12.2. Useful Websites

http://www.nist.gov/el/isd/ieee/ieee1588.cfm

The IEEE 1588 Standard.
PART VI. MONITORING AND AUTOMATION

This part describes various tools that allow system administrators to monitor system performance, automate system tasks, and report bugs.
CHAPTER 19. SYSTEM MONITORING TOOLS

In order to configure the system, system administrators often need to determine the amount of free memory, how much free disk space is available, how the hard drive is partitioned, or what processes are running.

19.1. VIEWING SYSTEM PROCESSES

19.1.1. Using the ps Command

The `ps` command allows you to display information about running processes. It produces a static list, that is, a snapshot of what is running when you execute the command. If you want a constantly updated list of running processes, use the `top` command or the System Monitor application instead.

To list all processes that are currently running on the system including processes owned by other users, type the following at a shell prompt:

```
ps ax
```

For each listed process, the `ps ax` command displays the process ID (PID), the terminal that is associated with it (TTY), the current status (STAT), the cumulated CPU time (TIME), and the name of the executable file (COMMAND). For example:

```
USER  PID %CPU %MEM    VSZ   RSS TTY   STAT START   TIME COMMAND
root    1  0.3  0.3 134776  6840 ?     Ss   09:28   0:01
        2  0.0  0.0      0     0 ?     S    09:28   0:00 [kthreadd]
        3  0.0  0.0      0     0 ?     S    09:28   0:00 [ksoftirqd/0]
        5  0.0  0.0      0     0 ?     S>   09:28   0:00 [kworker/0:0H]
```

To display the owner alongside each process, use the following command:

```
ps aux
```

Apart from the information provided by the `ps ax` command, `ps aux` displays the effective user name of the process owner (USER), the percentage of the CPU (%CPU) and memory (%MEM) usage, the virtual memory size in kilobytes (VSZ), the non-swapped physical memory size in kilobytes (RSS), and the time or date the process was started. For example:

```
USER  PID %CPU %MEM    VSZ   RSS TTY   STAT START   TIME COMMAND
root    1  0.3  0.3 134776  6840 ?     Ss   09:28   0:01
        2  0.0  0.0      0     0 ?     S    09:28   0:00 [kthreadd]
        3  0.0  0.0      0     0 ?     S    09:28   0:00 [ksoftirqd/0]
        5  0.0  0.0      0     0 ?     S>   09:28   0:00 [kworker/0:0H]
```

You can also use the `ps` command in a combination with `grep` to see if a particular process is running. For example, to determine if Emacs is running, type:
For a complete list of available command line options, see the ps(1) manual page.

### 19.1.2. Using the top Command

The `top` command displays a real-time list of processes that are running on the system. It also displays additional information about the system uptime, current CPU and memory usage, or total number of running processes, and allows you to perform actions such as sorting the list or killing a process.

To run the `top` command, type the following at a shell prompt:

```
$ top
```

For each listed process, the `top` command displays the process ID (PID), the effective user name of the process owner (USER), the priority (PR), the nice value (NI), the amount of virtual memory the process uses (VIRT), the amount of non-swapped physical memory the process uses (RES), the amount of shared memory the process uses (SHR), the process status field (S), the percentage of the CPU (%CPU) and memory (%MEM) usage, the cumulated CPU time (TIME+), and the name of the executable file (COMMAND). For example:

```
$ top
```

```
top - 16:42:12 up 13 min, 2 users, load average: 0.67, 0.31, 0.19
Tasks: 165 total, 2 running, 163 sleeping, 0 stopped, 0 zombie
%Cpu(s): 37.5 us, 3.0 sy, 0.0 ni, 59.5 id, 0.0 wa, 0.0 hi, 0.0 si, 0.0 st
KiB Mem : 1016800 total, 77368 free, 728936 used, 210496 buff/cache
KiB Swap: 839676 total, 776896 free, 62880 used, 122628 avail Mem

</table>

19.1.3. Using the System Monitor Tool

The Processes tab of the System Monitor tool allows you to view, search for, change the priority of, and kill processes from the graphical user interface.

To start the System Monitor tool from the command line, type `gnome-system-monitor` at a shell prompt. The System Monitor tool appears. Alternatively, if using the GNOME desktop, press the Super key to enter the Activities Overview, type `System Monitor` and then press Enter. The System Monitor tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Spacebar.

Click the Processes tab to view the list of running processes.
For each listed process, the System Monitor tool displays its name (Process Name), current status (Status), percentage of the CPU usage (% CPU), nice value (Nice), process ID (ID), memory usage (Memory), the channel the process is waiting in (Waiting Channel), and additional details about the session (Session). To sort the information by a specific column in ascending order, click the name of that column. Click the name of the column again to toggle the sort between ascending and descending order.

By default, the System Monitor tool displays a list of processes that are owned by the current user. Selecting various options from the View menu allows you to:

- view only active processes,
- view all processes,
- view your processes,
- view process dependencies,

Additionally, two buttons enable you to:

- refresh the list of processes,
- end a process by selecting it from the list and then clicking the End Process button.

### 19.2. VIEWING MEMORY USAGE

#### 19.2.1. Using the `free` Command

The `free` command allows you to display the amount of free and used memory on the system. To do so, type the following at a shell prompt:

```bash
free
```
The `free` command provides information about both the physical memory (Mem) and swap space (Swap). It displays the total amount of memory (total), as well as the amount of memory that is in use (used), free (free), shared (shared), sum of buffers and cached (buff/cache), and available (available). For example:

```
$ free
```

```
available total used free shared buff/cache available
Mem: 1016800 727300 84684 3500 204816 124068
Swap: 839676 66920 772756
```

By default, `free` displays the values in kilobytes. To display the values in megabytes, supply the `-m` command line option:

```
$ free -m
```

```
available total used free shared buff/cache available
Mem: 992 711 81 3 200 120
Swap: 819 65 754
```

For a complete list of available command line options, see the `free(1)` manual page.

### 19.2.2. Using the System Monitor Tool

The Resources tab of the System Monitor tool allows you to view the amount of free and used memory on the system.

To start the System Monitor tool from the command line, type `gnome-system-monitor` at a shell prompt. The System Monitor tool appears. Alternatively, if using the GNOME desktop, press the Super key to enter the Activities Overview, type System Monitor and then press Enter. The System Monitor tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Spacebar.

Click the Resources tab to view the system's memory usage.
In the Memory and Swap History section, the System Monitor tool displays a graphical representation of the memory and swap usage history, as well as the total amount of the physical memory (Memory) and swap space (Swap) and how much of it is in use.

19.3. VIEWING CPU USAGE

19.3.1. Using the System Monitor Tool

The Resources tab of the System Monitor tool allows you to view the current CPU usage on the system.

To start the System Monitor tool from the command line, type `gnome-system-monitor` at a shell prompt. The System Monitor tool appears. Alternatively, if using the GNOME desktop, press the Super key to enter the Activities Overview, type `System Monitor` and then press Enter. The System Monitor tool appears. The Super key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the Spacebar.

Click the Resources tab to view the system's CPU usage.

In the CPU History section, the System Monitor tool displays a graphical representation of the CPU usage history and shows the percentage of how much CPU is currently in use.

19.4. VIEWING BLOCK DEVICES AND FILE SYSTEMS

19.4.1. Using the lsblk Command

The lsblk command allows you to display a list of available block devices. It provides more information and better control on output formatting than the blkid command. It reads information from udev, therefore it is usable by non-root users. To display a list of block devices, type the
following at a shell prompt:

**lsblk**

For each listed block device, the `lsblk` command displays the device name (**NAME**), major and minor device number (**MAJ**: **MIN**), if the device is removable (**RM**), its size (**SIZE**), if the device is read-only (**RO**), what type it is (**TYPE**), and where the device is mounted (**MOUNTPOINT**). For example:

```
~$ lsblk
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sr0           11:0    1  1024M  0  rom
vda           252:0    0   20G   0  rom
  `-vda1       252:1    0  500M   0  part /boot
    `-vda2     252:2    0  19.5G  0  part
    |   `-vg_kvm-lv_root (dm-0) 253:0    0   18G   0  lvm /
    |`-vg_kvm-lv_swap (dm-1) 253:1    0  1.5G   0  lvm [SWAP]
```

By default, `lsblk` lists block devices in a tree-like format. To display the information as an ordinary list, add the `-l` command line option:

```
~$ lsblk -l
NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
sr0           11:0    1  1024M  0  rom
vda           252:0    0   20G   0  rom
vda1          252:1    0  500M   0  part /boot
vda2          252:2    0  19.5G  0  part
vg_kvm-lv_root (dm-0) 253:0    0   18G   0  lvm /
vg_kvm-lv_swap (dm-1) 253:1    0  1.5G   0  lvm [SWAP]
```

For a complete list of available command line options, see the `lsblk(8)` manual page.

### 19.4.2. Using the blkid Command

The `blkid` command allows you to display low-level information about available block devices. It requires root privileges, therefore non-root users should use the `lsblk` command. To do so, type the following at a shell prompt as root:

**blkid**

For each listed block device, the `blkid` command displays available attributes such as its universally unique identifier (**UUID**), file system type (**TYPE**), or volume label (**LABEL**). For example:

```
~# blkid
/dev/vda1: UUID="7fa9c421-0054-4555-b0ca-b470a97a3d84" TYPE="ext4"
/dev/vda2: UUID="7IvYzk-TnnK-oPjf-1pdD-cofz-DXaJ-gPdgBW" TYPE="LVM2_member"
/dev/mapper/vg_kvm-lv_root: UUID="a07b967c-71a0-4925-ab02-aebcad2ae824"
```
By default, the `blkid` command lists all available block devices. To display information about a particular device only, specify the device name on the command line:

```
blkid device_name
```

For instance, to display information about `/dev/vda1`, type as root:

```
~]# blkid /dev/vda1
/dev/vda1: UUID="7fa9c421-0054-4555-b0ca-b470a97a3d84" TYPE="ext4"
```

You can also use the above command with the `-p` and `-o udev` command line options to obtain more detailed information. Note that root privileges are required to run this command:

```
blkid -po udev device_name
```

For example:

```
~]# blkid -po udev /dev/vda1
ID_FS_UUID=7fa9c421-0054-4555-b0ca-b470a97a3d84
ID_FS_UUID_ENC=7fa9c421-0054-4555-b0ca-b470a97a3d84
ID_FS_VERSION=1.0
ID_FS_TYPE=ext4
ID_FS_USAGE=filesystem
```

For a complete list of available command line options, see the `blkid(8)` manual page.

### 19.4.3. Using the `findmnt` Command

The `findmnt` command allows you to display a list of currently mounted file systems. To do so, type the following at a shell prompt:

```
findmnt
```

For each listed file system, the `findmnt` command displays the target mount point (`TARGET`), source device (`SOURCE`), file system type (`FSTYPE`), and relevant mount options (`OPTIONS`). For example:

```
~]$ findmnt
TARGET            SOURCE             FSTYPE
OPTIONS
/                 /dev/mapper/rhel-root xfs
rw,relatime,seclabel,attr2,inode64,noquota
└─/proc            proc               proc
rw,nosuid,nodev,noexec,relatime
  └─/proc/sys/fs/binfmt_misc systemd-1 autofs
    rw,relatime,fd=32,pgrp=1,timeout=300,minproto=5,maxproto=5,direct
  └─/proc/fs/nfsd  sunrpc             nfsd
rw,relatime
  └─/sys            sysfs              sysfs
```
By default, `findmnt` lists file systems in a tree-like format. To display the information as an ordinary list, add the `-l` command line option:

```
findmnt -l
```

For instance:

```
TARGET SOURCE FSTYPE OPTIONS
/proc proc proc
rw, nosuid, nodev, noexec, relatime
/sys sysfs sysfs
rw, nosuid, nodev, noexec, relatime, seclabel
/dev/devtmpfs devtmpfs
rw, nosuid, seclabel, size=933372k, nr_inodes=233343, mode=755
/sys/kernel/security/securityfs securityfs
rw, nosuid, nodev, noexec, relatime
/dev/shm tmpfs tmpfs
rw, nosuid, nodev, seclabel
/dev/pts devpts devpts
rw, nosuid, nodev, noexec, relatime, seclabel, gid=5, mode=620, ptmxmode=000
/run tmpfs tmpfs
rw, nosuid, nodev, seclabel, mode=755
/sys/fs/cgroup tmpfs tmpfs
rw, nosuid, nodev, noexec, seclabel, mode=755
```

You can also choose to list only file systems of a particular type. To do so, add the `-t` command line option followed by a file system type:

```
findmnt -t type
```

For example, to list all xfs file systems, type:

```
findmnt -t xfs
```

For a complete list of available command line options, see the `findmnt(8)` manual page.

### 19.4.4. Using the df Command

The `df` command allows you to display a detailed report on the system's disk space usage. To do so, type the following at a shell prompt:
df

For each listed file system, the df command displays its name (Filesystem), size (1K-blocks or Size), how much space is used (Used), how much space is still available (Available), the percentage of space usage (Use%), and where is the file system mounted (Mounted on). For example:

```
[-] df
Filesystem                 1K-blocks      Used    Available  Use%   Mounted on
/dev/mapper/vg_kvm-lv_root  18618236   4357360  13315112  25%      /
/tmpfs                      380376       288    380088   1%       /dev/shm
/dev/vda1                   495844     77029    393215  17%      /boot
```

By default, the df command shows the partition size in 1 kilobyte blocks and the amount of used and available disk space in kilobytes. To view the information in megabytes and gigabytes, supply the -h command line option, which causes df to display the values in a human-readable format:

```
[-] df -h
Filesystem                  Size   Used   Avail  Use%   Mounted on
/dev/mapper/vg_kvm-lv_root   18G    4.2G   13G   25%      /
/tmpfs                       372M   288K    372M   1%       /dev/shm
/dev/vda1                   485M    76M   384M   17%      /boot
```

For a complete list of available command line options, see the df(1) manual page.

19.4.5. Using the du Command

The du command allows you to displays the amount of space that is being used by files in a directory. To display the disk usage for each of the subdirectories in the current working directory, run the command with no additional command line options:

```
[-] du
14972   ./Downloads
4       ./mozilla/extensions
4       ./mozilla/plugins
12      ./mozilla
15004   .
```

By default, the du command displays the disk usage in kilobytes. To view the information in megabytes and gigabytes, supply the -h command line option, which causes the utility to display the values in a human-readable format:

```
[-] du -h
```

For instance:
At the end of the list, the `du` command always shows the grand total for the current directory. To display only this information, supply the `-s` command line option:

```
$ du -sh
```

For example:

```
$ du -sh
15M .
```

For a complete list of available command line options, see the `du(1)` manual page.

### 19.4.6. Using the System Monitor Tool

The **File** Systems tab of the **System Monitor** tool allows you to view file systems and disk space usage in the graphical user interface.

To start the **System Monitor** tool from the command line, type `gnome-system-monitor` at a shell prompt. The **System Monitor** tool appears. Alternatively, if using the GNOME desktop, press the **Super** key to enter the Activities Overview, type **System Monitor** and then press **Enter**. The **System Monitor** tool appears. The **Super** key appears in a variety of guises, depending on the keyboard and other hardware, but often as either the Windows or Command key, and typically to the left of the **Spacebar**.

Click the **File** Systems tab to view a list of file systems.

![System Monitor — File Systems](image)

**Figure 19.3. System Monitor — File Systems**

For each listed file system, the **System Monitor** tool displays the source device (Device), target mount point (Directory), and file system type (Type), as well as its size (Total), and how much space is available (Available), and used (Used).
19.5. VIEWING HARDWARE INFORMATION

19.5.1. Using the lspci Command

The `lspci` command allows you to display information about PCI buses and devices that are attached to them. To list all PCI devices that are in the system, type the following at a shell prompt:

```
$ lspci
```

This displays a simple list of devices, for example:

```
00:00.0 Host bridge: Intel Corporation 82X38/X48 Express DRAM Controller
00:01.0 PCI bridge: Intel Corporation 82X38/X48 Express Host-Primary PCI Express Bridge
00:1a.0 USB Controller: Intel Corporation 82801I (ICH9 Family) USB UHCI Controller #4 (rev 02)
00:1a.1 USB Controller: Intel Corporation 82801I (ICH9 Family) USB UHCI Controller #5 (rev 02)
00:1a.2 USB Controller: Intel Corporation 82801I (ICH9 Family) USB UHCI Controller #6 (rev 02)
```

You can also use the `-v` command line option to display more verbose output, or `-vv` for very verbose output:

```
$ lspci -v
```

For instance, to determine the manufacturer, model, and memory size of a system's video card, type:

```
$ lspci -v
```

```
01:00.0 VGA compatible controller: nVidia Corporation G84 [Quadro FX 370] (rev a1) (prog-if 00 [VGA controller])
Subsystem: nVidia Corporation Device 0491
Physical Slot: 2
Flags: bus master, fast devsel, latency 0, IRQ 16
Memory at f2000000 (32-bit, non-prefetchable) [size=16M]
Memory at e0000000 (64-bit, prefetchable) [size=256M]
Memory at f0000000 (64-bit, non-prefetchable) [size=32M]
I/O ports at 1100 [size=128]
Expansion ROM at <unassigned> [disabled]
Capabilities: <access denied>
Kernel driver in use: nouveau
Kernel modules: nouveau, nvidiafb
```

For a complete list of available command line options, see the `lspci(8)` manual page.

19.5.2. Using the lsusb Command
The `lsusb` command allows you to display information about USB buses and devices that are attached to them. To list all USB devices that are in the system, type the following at a shell prompt:

```
lsusb
```

This displays a simple list of devices, for example:

```
[output truncated]
Bus 001 Device 001: ID 1d6b:0002 Linux Foundation 2.0 root hub
Bus 002 Device 001: ID 1d6b:0002 Linux Foundation 2.0 root hub
Bus 001 Device 002: ID 0bda:0151 Realtek Semiconductor Corp. Mass Storage Device (Multicard Reader)
Bus 008 Device 002: ID 03f0:2c24 Hewlett-Packard Logitech M-UAL-96 Mouse
Bus 008 Device 003: ID 04b3:3025 IBM Corp.
```

You can also use the `-v` command line option to display more verbose output:

```
lsusb -v
```

For instance:

```
[output truncated]
Bus 008 Device 002: ID 03f0:2c24 Hewlett-Packard Logitech M-UAL-96 Mouse
Device Descriptor:
  bLength 18
  bDescriptorType 1
  bcdUSB 2.00
  bDeviceClass 0 (Defined at Interface level)
  bDeviceSubClass 0
  bDeviceProtocol 0
  bMaxPacketSize0 8
  idVendor 0x03f0 Hewlett-Packard
  idProduct 0x2c24 Logitech M-UAL-96 Mouse
  bcdDevice 31.00
  iManufacturer 1
  iProduct 2
  iSerial 0
  bNumConfigurations 1
  Configuration Descriptor:
    bLength 9
    bDescriptorType 2
    [output truncated]
```

For a complete list of available command line options, see the `lsusb(8)` manual page.

### 19.5.3. Using the lscpu Command

The `lscpu` command allows you to list information about CPUs that are present in the system, including the number of CPUs, their architecture, vendor, family, model, CPU caches, etc. To do so, type the following at a shell prompt:

```
lscpu
```
1. lscpu

For example:

```
~]$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                4
On-line CPU(s) list:   0-3
Thread(s) per core:    1
Core(s) per socket:    4
Socket(s):             1
NUMA node(s):          1
Vendor ID:             GenuineIntel
CPU family:            6
Model:                 23
Stepping:              7
CPU MHz:               1998.000
BogoMIPS:              4999.98
Virtualization:        VT-x
L1d cache:             32K
L1i cache:             32K
L2 cache:              3072K
NUMA node0 CPU(s):     0-3
```

For a complete list of available command line options, see the `lscpu(1)` manual page.

## 19.6. CHECKING FOR HARDWARE ERRORS

Red Hat Enterprise Linux 7 introduced the new *hardware event report mechanism* (HERM). This mechanism gathers system-reported memory errors as well as errors reported by the *error detection and correction* (EDAC) mechanism for dual in-line memory modules (DIMMs) and reports them to user space. The user-space daemon `rasdaemon`, catches and handles all *reliability, availability, and serviceability* (RAS) error events that come from the kernel tracing mechanism, and logs them. The functions previously provided by `edac-utils` are now replaced by `rasdaemon`.

To install `rasdaemon`, enter the following command as `root`:

```
~]# yum install rasdaemon
```

Start the service as follows:

```
~]# systemctl start rasdaemon
```

To make the service run at system start, enter the following command:

```
~]# systemctl enable rasdaemon
```

The `ras-mc-ctl` utility provides a means to work with EDAC drivers. Enter the following command to see a list of command options:

```
~]# ras-mc-ctl --help
```
Usage: ras-mc-ctl [OPTIONS...]
   --quiet    Quiet operation.
   --mainboard Print mainboard vendor and model for this hardware.
   --status   Print status of EDAC drivers.

To view a summary of memory controller events, run as root:

~-~-# ras-mc-ctl --summary
Memory controller events summary:
   Corrected on DIMM Label(s): 'CPU_SrcID#0_Ha#0_Ch#0_DIMM#0'
   location: 0:0:0:-1 errors: 1

No PCIe AER errors.

No Extlog errors.
MCE records summary:
   1 MEMORY CONTROLLER RD_CHANNEL0_ERR Transaction: Memory read error
   errors
   2 No Error errors

To view a list of errors reported by the memory controller, run as root:

~-~-# ras-mc-ctl --errors
Memory controller events:
   1 3172-02-17 00:47:01 -0500 1 Corrected error(s): memory read error at
     CPU_SrcID#0_Ha#0_Ch#0_DIMM#0 location: 0:0:0:-1, addr 65928, grain 7,
     syndrome 0  area:DRAM err_code:0001:0090 socket:0 ha:0 channel_mask:1
     rank:0

No PCIe AER errors.

No Extlog errors.

MCE events:
   1 3171-11-09 06:20:21 -0500 error: MEMORY CONTROLLER RD_CHANNEL0_ERR
     Transaction: Memory read error, mcg mcgstatus=0, mci Corrected_error,
     n_errors=1, mcgcap=0x01000c16, status=0x8c00004000010090, addr=0x1018893000,
     misc=0x15020a086, walltime=0x57e96780, cpuid=0x00050663, bank=0x00000007
   2 3205-06-22 00:13:41 -0400 error: No Error, mcg mcgstatus=0, mci
     Corrected_error Error_enabled, mcgcap=0x01000c16, status=0x9400000000000000,
     addr=0x0000abcd, walltime=0x57e967ea, cpuid=0x00050663, bank=0x00000001
   3 3205-06-22 00:13:41 -0400 error: No Error, mcg mcgstatus=0, mci
     Corrected_error Error_enabled, mcgcap=0x01000c16, status=0x9400000000000000,
     addr=0x00001234, walltime=0x57e967ea, cpu=0x00000001, cpuid=0x00050663, apicid=0x00000002, bank=0x00000002

These commands are also described in the `ras-mc-ctl(8)` manual page.

## 19.7. Monitoring Performance with Net-SNMP

Red Hat Enterprise Linux 7 includes the Net-SNMP software suite, which includes a flexible and
extensible simple network management protocol (SNMP) agent. This agent and its associated utilities can be used to provide performance data from a large number of systems to a variety of tools which support polling over the SNMP protocol.

This section provides information on configuring the Net-SNMP agent to securely provide performance data over the network, retrieving the data using the SNMP protocol, and extending the SNMP agent to provide custom performance metrics.

19.7.1. Installing Net-SNMP

The Net-SNMP software suite is available as a set of RPM packages in the Red Hat Enterprise Linux software distribution. Table 19.2, “Available Net-SNMP packages” summarizes each of the packages and their contents.

Table 19.2. Available Net-SNMP packages

<table>
<thead>
<tr>
<th>Package</th>
<th>Provides</th>
</tr>
</thead>
<tbody>
<tr>
<td>net-snmp</td>
<td>The SNMP Agent Daemon and documentation. This package is required for exporting performance data.</td>
</tr>
<tr>
<td>net-snmp-libs</td>
<td>The netsnmp library and the bundled management information bases (MIBs). This package is required for exporting performance data.</td>
</tr>
<tr>
<td>net-snmp-utils</td>
<td>SNMP clients such as snmpget and snmpwalk. This package is required in order to query a system’s performance data over SNMP.</td>
</tr>
<tr>
<td>net-snmp-perl</td>
<td>The mib2c utility and the NetSNMP Perl module. Note that this package is provided by the Optional channel. See Section 8.5.7, “Adding the Optional and Supplementary Repositories” for more information on Red Hat additional channels.</td>
</tr>
<tr>
<td>net-snmp-python</td>
<td>An SNMP client library for Python. Note that this package is provided by the Optional channel. See Section 8.5.7, “Adding the Optional and Supplementary Repositories” for more information on Red Hat additional channels.</td>
</tr>
</tbody>
</table>

To install any of these packages, use the yum command in the following form:

```
yum install package...
```

For example, to install the SNMP Agent Daemon and SNMP clients used in the rest of this section, type the following at a shell prompt as root:

```
~]# yum install net-snmp net-snmp-libs net-snmp-utils
```

For more information on how to install new packages in Red Hat Enterprise Linux, see Section 8.2.4, “Installing Packages”.

19.7.2. Running the Net-SNMP Daemon

The net-snmp package contains snmpd, the SNMP Agent Daemon. This section provides information on how to start, stop, and restart the snmpd service. For more information on managing system
services in Red Hat Enterprise Linux 7, see Chapter 9, Managing Services with systemd.

19.7.2.1. Starting the Service

To run the `snmpd` service in the current session, type the following at a shell prompt as `root`:

```
systemctl start snmpd.service
```

To configure the service to be automatically started at boot time, use the following command:

```
systemctl enable snmpd.service
```

19.7.2.2. Stopping the Service

To stop the running `snmpd` service, type the following at a shell prompt as `root`:

```
systemctl stop snmpd.service
```

To disable starting the service at boot time, use the following command:

```
systemctl disable snmpd.service
```

19.7.2.3. Restarting the Service

To restart the running `snmpd` service, type the following at a shell prompt:

```
systemctl restart snmpd.service
```

This command stops the service and starts it again in quick succession. To only reload the configuration without stopping the service, run the following command instead:

```
systemctl reload snmpd.service
```

This causes the running `snmpd` service to reload its configuration.

19.7.3. Configuring Net-SNMP

To change the Net-SNMP Agent Daemon configuration, edit the `/etc/snmp/snmpd.conf` configuration file. The default `snmpd.conf` file included with Red Hat Enterprise Linux 7 is heavily commented and serves as a good starting point for agent configuration.

This section focuses on two common tasks: setting system information and configuring authentication. For more information about available configuration directives, see the `snmpd.conf(5)` manual page. Additionally, there is a utility in the net-snmp package named `snmpconf` which can be used to interactively generate a valid agent configuration.

Note that the net-snmp-utils package must be installed in order to use the `snmpwalk` utility described in this section.
NOTE

For any changes to the configuration file to take effect, force the `snmpd` service to re-read the configuration by running the following command as `root`:

```
systemctl reload snmpd.service
```

### 19.7.3.1. Setting System Information

Net-SNMP provides some rudimentary system information via the `system` tree. For example, the following `snmpwalk` command shows the `system` tree with a default agent configuration.

```
~]# snmpwalk -v2c -c public localhost system
SNMPv2-MIB::sysDescr.0 = STRING: Linux localhost.localdomain 3.10.0-123.el7.x86_64 #1 SMP Mon May 5 11:16:57 EDT 2014 x86_64
SNMPv2-MIB::sysObjectID.0 = OID: NET-SNMP-MIB::netSnmpAgentOIDs.10
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (464) 0:00:04.64
SNMPv2-MIB::sysContact.0 = STRING: Root <root@localhost> (configure /etc/snmp/snmp.local.conf)
[output truncated]
```

By default, the `sysName` object is set to the host name. The `sysLocation` and `sysContact` objects can be configured in the `/etc/snmp/snmpd.conf` file by changing the value of the `syslocation` and `syscontact` directives, for example:

```
syslocation Datacenter, Row 4, Rack 3
syscontact UNIX Admin <admin@example.com>
```

After making changes to the configuration file, reload the configuration and test it by running the `snmpwalk` command again:

```
~]# systemctl reload snmp.service
~]# snmpwalk -v2c -c public localhost system
SNMPv2-MIB::sysDescr.0 = STRING: Linux localhost.localdomain 3.10.0-123.el7.x86_64 #1 SMP Mon May 5 11:16:57 EDT 2014 x86_64
SNMPv2-MIB::sysObjectID.0 = OID: NET-SNMP-MIB::netSnmpAgentOIDs.10
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (35424) 0:05:54.24
SNMPv2-MIB::sysContact.0 = STRING: UNIX Admin <admin@example.com>
SNMPv2-MIB::sysName.0 = STRING: localhost.localdomain
SNMPv2-MIB::sysLocation.0 = STRING: Datacenter, Row 4, Rack 3
[output truncated]
```

### 19.7.3.2. Configuring Authentication

The Net-SNMP Agent Daemon supports all three versions of the SNMP protocol. The first two versions (1 and 2c) provide for simple authentication using a `community string`. This string is a shared secret between the agent and any client utilities. The string is passed in clear text over the network however and is not considered secure. Version 3 of the SNMP protocol supports user authentication and message encryption using a variety of protocols. The Net-SNMP agent also supports tunneling over SSH, TLS authentication with X.509 certificates, and Kerberos authentication.

**Configuring SNMP Version 2c Community**
To configure an **SNMP version 2c community**, use either the `rocommunity` or `rwcommunity` directive in the `/etc/snmp/snmpd.conf` configuration file. The format of the directives is as follows:

```
directive community [source [OID]]
```

... where `community` is the community string to use, `source` is an IP address or subnet, and `OID` is the SNMP tree to provide access to. For example, the following directive provides read-only access to the `system` tree to a client using the community string “redhat” on the local machine:

```
rocommunity redhat 127.0.0.1 .1.3.6.1.2.1.1
```

To test the configuration, use the `snmpwalk` command with the `-v` and `-c` options.

```
~# snmpwalk -v2c -c redhat localhost system
SNMPv2-MIB::sysDescr.0 = STRING: Linux localhost.localdomain 3.10.0-123.el7.x86_64 #1 SMP Mon May 5 11:16:57 EDT 2014 x86_64
SNMPv2-MIB::sysObjectID.0 = OID: NET-SNMP-MIB::netSnmpAgentOIDs.10
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (101376) 0:16:53.76
SNMPv2-MIB::sysContact.0 = STRING: UNIX Admin <admin@example.com>
SNMPv2-MIB::sysName.0 = STRING: localhost.localdomain
SNMPv2-MIB::sysLocation.0 = STRING: Datacenter, Row 4, Rack 3
```

Configuring SNMP Version 3 User

To configure an **SNMP version 3 user**, use the `net-snmp-create-v3-user` command. This command adds entries to the `/var/lib/net-snmp/snmpd.conf` and `/etc/snmp/snmpd.conf` files which create the user and grant access to the user. Note that the `net-snmp-create-v3-user` command may only be run when the agent is not running. The following example creates the “admin” user with the password “redhatsnmp”:

```
~# systemctl stop snmpd.service
~# net-snmp-create-v3-user
Enter a SNMPv3 user name to create: admin
Enter authentication pass-phrase: redhatsnmp
Enter encryption pass-phrase: [press return to reuse the authentication pass-phrase]
adding the following line to /var/lib/net-snmp/snmpd.conf:
createUser admin MD5 "redhatsnmp" DES
adding the following line to /etc/snmp/snmpd.conf:
rwuser admin
~# systemctl start snmpd.service
```

The `rwuser` directive (or `rouser` when the `-ro` command line option is supplied) that `net-snmp-create-v3-user` adds to `/etc/snmp/snmpd.conf` has a similar format to the `rwcommunity` and `rocommunity` directives:

```
directive user [noauth|auth|priv] [OID]
```

... where `user` is a user name and `OID` is the SNMP tree to provide access to. By default, the Net-SNMP Agent Daemon allows only authenticated requests (the `auth` option). The `noauth` option allows you to
permit unauthenticated requests, and the `priv` option enforces the use of encryption. The `authpriv` option specifies that requests must be authenticated and replies should be encrypted.

For example, the following line grants the user “admin” read-write access to the entire tree:

```
rwuser admin authpriv .1
```

To test the configuration, create a `.snmp/` directory in your user’s home directory and a configuration file named `snmp.conf` in that directory (`~/.snmp/snmp.conf`) with the following lines:

```
defVersion 3
defSecurityLevel authPriv
defSecurityName admin
defPassphrase redhatsnmp
```

The `snmpwalk` command will now use these authentication settings when querying the agent:

```
$ snmpwalk -v3 localhost system
SNMPv2-MIB::sysDescr.0 = STRING: Linux localhost.localdomain 3.10.0-123.el7.x86_64 #1 SMP Mon May 5 11:16:57 EDT 2014 x86_64
[output truncated]
```

19.7.4. Retrieving Performance Data over SNMP

The Net-SNMP Agent in Red Hat Enterprise Linux provides a wide variety of performance information over the SNMP protocol. In addition, the agent can be queried for a listing of the installed RPM packages on the system, a listing of currently running processes on the system, or the network configuration of the system.

This section provides an overview of OIDs related to performance tuning available over SNMP. It assumes that the `net-snmp-utils` package is installed and that the user is granted access to the SNMP tree as described in Section 19.7.3.2, “Configuring Authentication”.

19.7.4.1. Hardware Configuration

The Host Resources MIB included with Net-SNMP presents information about the current hardware and software configuration of a host to a client utility. Table 19.3, “Available OIDs” summarizes the different OIDs available under that MIB.

<table>
<thead>
<tr>
<th>OID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST-RESOURCES-MIB::hrSystem</td>
<td>Contains general system information such as uptime, number of users, and number of running processes.</td>
</tr>
<tr>
<td>HOST-RESOURCES-MIB::hrStorage</td>
<td>Contains data on memory and file system usage.</td>
</tr>
<tr>
<td>HOST-RESOURCES-MIB::hrDevices</td>
<td>Contains a listing of all processors, network devices, and file systems.</td>
</tr>
</tbody>
</table>
There are also a number of SNMP tables available in the Host Resources MIB which can be used to retrieve a summary of the available information. The following example displays HOST-RESOURCES-MIB::hrFSTable:

```bash
[-]$ snmptable -Cb localhost HOST-RESOURCES-MIB::hrFSTable
SNMP table: HOST-RESOURCES-MIB::hrFSTable

<table>
<thead>
<tr>
<th>Index</th>
<th>MountPoint</th>
<th>RemoteMountPoint</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&quot;/&quot;</td>
<td></td>
<td>HOST-RESOURCES-TYPES::hrFSLinuxExt2</td>
</tr>
<tr>
<td>readWrite</td>
<td>true</td>
<td>31</td>
<td>0-1-1,0:0:0.0</td>
</tr>
<tr>
<td>5</td>
<td>&quot;/dev/shm&quot;</td>
<td></td>
<td>HOST-RESOURCES-TYPES::hrFSOther</td>
</tr>
<tr>
<td>readWrite</td>
<td>false</td>
<td>35</td>
<td>0-1-1,0:0:0.0</td>
</tr>
<tr>
<td>6</td>
<td>&quot;/boot&quot;</td>
<td></td>
<td>HOST-RESOURCES-TYPES::hrFSLinuxExt2</td>
</tr>
<tr>
<td>readWrite</td>
<td>false</td>
<td>36</td>
<td>0-1-1,0:0:0.0</td>
</tr>
</tbody>
</table>
```

For more information about HOST-RESOURCES-MIB, see the `/usr/share/snmp/mibs/HOST-RESOURCES-MIB.txt` file.

### 19.7.4.2. CPU and Memory Information

Most system performance data is available in the UCD SNMP MIB. The systemStats OID provides a number of counters around processor usage:

```bash
[-]$ snmpwalk localhost UCD-SNMP-MIB::systemStats
UCD-SNMP-MIB::ssIndex.0 = INTEGER: 1
UCD-SNMP-MIB::ssErrorName.0 = STRING: systemStats
UCD-SNMP-MIB::ssSwapIn.0 = INTEGER: 0 kB
UCD-SNMP-MIB::ssSwapOut.0 = INTEGER: 0 kB
UCD-SNMP-MIB::ssIOSent.0 = INTEGER: 0 blocks/s
UCD-SNMP-MIB::ssIOReceive.0 = INTEGER: 0 blocks/s
UCD-SNMP-MIB::ssSysInterrupts.0 = INTEGER: 29 interrupts/s
UCD-SNMP-MIB::ssSysContext.0 = INTEGER: 18 switches/s
UCD-SNMP-MIB::ssCpuUser.0 = INTEGER: 0
UCD-SNMP-MIB::ssCpuSystem.0 = INTEGER: 0
UCD-SNMP-MIB::ssCpuIdle.0 = INTEGER: 99
UCD-SNMP-MIB::ssCpuRawUser.0 = Counter32: 2278
UCD-SNMP-MIB::ssCpuRawNice.0 = Counter32: 1395
UCD-SNMP-MIB::ssCpuRawSystem.0 = Counter32: 6826
UCD-SNMP-MIB::ssCpuRawIdle.0 = Counter32: 3383736
UCD-SNMP-MIB::ssCpuRawWait.0 = Counter32: 7629
UCD-SNMP-MIB::ssCpuRawKernel.0 = Counter32: 0
UCD-SNMP-MIB::ssCpuRawInterrupt.0 = Counter32: 434
```
In particular, the `ssCpuRawUser`, `ssCpuRawSystem`, `ssCpuRawWait`, and `ssCpuRawIdle` OIDs provide counters which are helpful when determining whether a system is spending most of its processor time in kernel space, user space, or I/O. `ssRawSwapIn` and `ssRawSwapOut` can be helpful when determining whether a system is suffering from memory exhaustion.

More memory information is available under the `UCD-SNMP-MIB::memory` OID, which provides similar data to the `free` command:

```bash
$ snmpwalk localhost UCD-SNMP-MIB::memory
UCD-SNMP-MIB::memIndex.0 = INTEGER: 0
UCD-SNMP-MIB::memErrorName.0 = STRING: swap
UCD-SNMP-MIB::memTotalSwap.0 = INTEGER: 1023992 kB
UCD-SNMP-MIB::memAvailSwap.0 = INTEGER: 1023992 kB
UCD-SNMP-MIB::memTotalReal.0 = INTEGER: 1021588 kB
UCD-SNMP-MIB::memAvailReal.0 = INTEGER: 634260 kB
UCD-SNMP-MIB::memTotalFree.0 = INTEGER: 1658252 kB
UCD-SNMP-MIB::memMinimumSwap.0 = INTEGER: 16000 kB
UCD-SNMP-MIB::memBuffer.0 = INTEGER: 30760 kB
UCD-SNMP-MIB::memCached.0 = INTEGER: 216200 kB
UCD-SNMP-MIB::memSwapError.0 = INTEGER: noError(0)
UCD-SNMP-MIB::memSwapErrorMsg.0 = STRING:
```

Load averages are also available in the `UCD SNMP MIB`. The SNMP table `UCD-SNMP-MIB::laTable` has a listing of the 1, 5, and 15 minute load averages:

```bash
$ snmptable localhost UCD-SNMP-MIB::laTable
SNMP table: UCD-SNMP-MIB::laTable

   laIndex laNames laLoad laConfig laLoadInt laLoadFloat laErrorFlag laErrMessage
    1  Load-1   0.00    12.00         0    0.000000     noError
    2  Load-5   0.00    12.00         0    0.000000     noError
    3 Load-15   0.00    12.00         0    0.000000     noError
```

19.7.4.3. File System and Disk Information

The `Host Resources MIB` provides information on file system size and usage. Each file system (and also each memory pool) has an entry in the `HOST-RESOURCES-MIB::hrStorageTable` table:

```bash
$ snmptable -Cb localhost HOST-RESOURCES-MIB::hrStorageTable
SNMP table: HOST-RESOURCES-MIB::hrStorageTable

   Index AllocationUnits Type Descr
     1        1024 Bytes 1021588 388064
   ? HOST-RESOURCES-TYPES::hrStorageRam Physical memory
```
The OIDs under `HOST-RESOURCES-MIB::hrStorageSize` and `HOST-RESOURCES-MIB::hrStorageUsed` can be used to calculate the remaining capacity of each mounted file system.

I/O data is available both in `UCD-SNMP-MIB::systemStats` (ssIORawSent.0 and ssIORawRecieved.0) and in `UCD-DISKIO-MIB::diskIOTable`. The latter provides much more granular data. Under this table are OIDs for `diskIONReadX` and `diskIONWrittenX`, which provide counters for the number of bytes read from and written to the block device in question since the system boot:

```
~]$ snmptable -Cb localhost UCD-DISKIO-MIB::diskIOTable
SNMP table: UCD-DISKIO-MIB::diskIOTable

Index  Device          NRead  NWritten  Reads  Writes  LA1  LA5  LA15  NReadX  NWrittenX
       25     sda 216886272 139109376 16409  4894  ?  ?  ?  216886272
139109376
       26     sda1 2455552  5120    613    2  ?  ?  ?   2455552
5120
       27     sda2 1486848    0     332    0  ?  ?  ?   1486848
0
       28     sda3 212321280 139104256 15312  4871  ?  ?  ?  212321280
139104256
```

19.7.4.4. Network Information

The `Interfaces MIB` provides information on network devices. `IF-MIB::ifTable` provides an SNMP table with an entry for each interface on the system, the configuration of the interface, and various packet counters for the interface. The following example shows the first few columns of `ifTable` on a system with two physical network interfaces:

```
~]$ snmptable -Cb localhost IF-MIB::ifTable
SNMP table: IF-MIB::ifTable

Index  Descr             Type   Mtu    Speed      PhysAddress AdminStatus
       1    lo softwareLoopback 16436 10000000       up
       2  eth0   ethernetCsmacd  1500        0 52:54:0:c7:69:58       up
       3  eth1   ethernetCsmacd  1500        0 52:54:0:a7:a3:24       down
```
Network traffic is available under the OIDs `IF-MIB::ifOutOctets` and `IF-MIB::ifInOctets`. The following SNMP queries will retrieve network traffic for each of the interfaces on this system:

```
~]$ snmpwalk localhost IF-MIB::ifDescr
IF-MIB::ifDescr.1 = STRING: lo
IF-MIB::ifDescr.2 = STRING: eth0
IF-MIB::ifDescr.3 = STRING: eth1
~]$ snmpwalk localhost IF-MIB::ifOutOctets
IF-MIB::ifOutOctets.1 = Counter32: 10060699
IF-MIB::ifOutOctets.2 = Counter32: 650
IF-MIB::ifOutOctets.3 = Counter32: 0
~]$ snmpwalk localhost IF-MIB::ifInOctets
IF-MIB::ifInOctets.1 = Counter32: 10060699
IF-MIB::ifInOctets.2 = Counter32: 78650
IF-MIB::ifInOctets.3 = Counter32: 0
```

19.7.5. Extending Net-SNMP

The Net-SNMP Agent can be extended to provide application metrics in addition to raw system metrics. This allows for capacity planning as well as performance issue troubleshooting. For example, it may be helpful to know that an email system had a 5-minute load average of 15 while being tested, but it is more helpful to know that the email system has a load average of 15 while processing 80,000 messages a second. When application metrics are available via the same interface as the system metrics, this also allows for the visualization of the impact of different load scenarios on system performance (for example, each additional 10,000 messages increases the load average linearly until 100,000).

A number of the applications included in Red Hat Enterprise Linux extend the Net-SNMP Agent to provide application metrics over SNMP. There are several ways to extend the agent for custom applications as well. This section describes extending the agent with shell scripts and the Perl plug-ins from the Optional channel. It assumes that the `net-snmp-utils` and `net-snmp-perl` packages are installed, and that the user is granted access to the SNMP tree as described in Section 19.7.3.2, “Configuring Authentication”.

19.7.5.1. Extending Net-SNMP with Shell Scripts

The Net-SNMP Agent provides an extension MIB (NET-SNMP-EXTEND-MIB) that can be used to query arbitrary shell scripts. To specify the shell script to run, use the `extend` directive in the `/etc/snmp/snmpd.conf` file. Once defined, the Agent will provide the exit code and any output of the command over SNMP. The example below demonstrates this mechanism with a script which determines the number of `httpd` processes in the process table.

```
NOTE

The Net-SNMP Agent also provides a built-in mechanism for checking the process table via the `proc` directive. See the `snmpd.conf(5)` manual page for more information.
```

The exit code of the following shell script is the number of `httpd` processes running on the system at a given point in time:

```
#!/bin/sh
NUMPIDS=`pgrep httpd | wc -l`
```
To make this script available over SNMP, copy the script to a location on the system path, set the executable bit, and add an `extend` directive to the `/etc/snmp/snmpd.conf` file. The format of the `extend` directive is the following:

```
extend name prog args
```

... where `name` is an identifying string for the extension, `prog` is the program to run, and `args` are the arguments to give the program. For instance, if the above shell script is copied to `/usr/local/bin/check_apache.sh`, the following directive will add the script to the SNMP tree:

```
extend httpd_pids /bin/sh /usr/local/bin/check_apache.sh
```

The script can then be queried at `NET-SNMP-EXTEND-MIB::nsExtendObjects`:

```
-]$ snmpwalk localhost NET-SNMP-EXTEND-MIB::nsExtendObjects
NET-SNMP-EXTEND-MIB::nsExtendNumEntries.0 = INTEGER: 1
NET-SNMP-EXTEND-MIB::nsExtendCommand."httpd_pids" = STRING: /bin/sh
/usr/local/bin/check_apache.sh
NET-SNMP-EXTEND-MIB::nsExtendArgs."httpd_pids" = STRING:
NET-SNMP-EXTEND-MIB::nsExtendCacheTime."httpd_pids" = INTEGER: 5
NET-SNMP-EXTEND-MIB::nsExtendExecType."httpd_pids" = INTEGER: exec(1)
NET-SNMP-EXTEND-MIB::nsExtendRunType."httpd_pids" = INTEGER: run-on-read(1)
NET-SNMP-EXTEND-MIB::nsExtendStorage."httpd_pids" = INTEGER: permanent(4)
NET-SNMP-EXTEND-MIB::nsExtendStatus."httpd_pids" = INTEGER: active(1)
NET-SNMP-EXTEND-MIB::nsExtendOutNumLines."httpd_pids" = INTEGER: 1
NET-SNMP-EXTEND-MIB::nsExtendResult."httpd_pids" = INTEGER: 8
NET-SNMP-EXTEND-MIB::nsExtendOutLine."httpd_pids".1 = STRING:
```

Note that the exit code (“8” in this example) is provided as an INTEGER type and any output is provided as a STRING type. To expose multiple metrics as integers, supply different arguments to the script using the `extend` directive. For example, the following shell script can be used to determine the number of processes matching an arbitrary string, and will also output a text string giving the number of processes:

```
#!/bin/sh

PATTERN=$1
NUMPIDS=`pgrep $PATTERN | wc -l`

echo "There are $NUMPIDS $PATTERN processes."
exit $NUMPIDS
```

The following `/etc/snmp/snmpd.conf` directives will give both the number of `httpd` PIDs as well as the number of `snmpd` PIDs when the above script is copied to `/usr/local/bin/check_proc.sh`:

```
extend httpd_pids /bin/sh /usr/local/bin/check_proc.sh httpd
extend snmpd_pids /bin/sh /usr/local/bin/check_proc.sh snmpd
```
The following example shows the output of an `snmpwalk` of the `nsExtendObjects` OID:

```
[-] $ snmpwalk localhost NET-SNMP-EXTEND-MIB::nsExtendObjects
NET-SNMP-EXTEND-MIB::nsExtendNumEntries.0 = INTEGER: 2
NET-SNMP-EXTEND-MIB::nsExtendCommand."httpd_pids" = STRING: /bin/sh
NET-SNMP-EXTEND-MIB::nsExtendCommand."snmpd_pids" = STRING: /bin/sh
NET-SNMP-EXTEND-MIB::nsExtendArgs."httpd_pids" = STRING:
/usr/local/bin/check_proc.sh httpd
NET-SNMP-EXTEND-MIB::nsExtendArgs."snmpd_pids" = STRING:
/usr/local/bin/check_proc.sh snmpd
NET-SNMP-EXTEND-MIB::nsExtendInput."httpd_pids" = STRING:
NET-SNMP-EXTEND-MIB::nsExtendInput."snmpd_pids" = STRING:
...
NET-SNMP-EXTEND-MIB::nsExtendResult."httpd_pids" = INTEGER: 8
NET-SNMP-EXTEND-MIB::nsExtendResult."snmpd_pids" = INTEGER: 1
NET-SNMP-EXTEND-MIB::nsExtendOutLine."httpd_pids".1 = STRING: There are 8 httpd processes.
NET-SNMP-EXTEND-MIB::nsExtendOutLine."snmpd_pids".1 = STRING: There are 1 snmpd processes.
```

**WARNING**

Integer exit codes are limited to a range of 0–255. For values that are likely to exceed 256, either use the standard output of the script (which will be typed as a string) or a different method of extending the agent.

This last example shows a query for the free memory of the system and the number of `httpd` processes. This query could be used during a performance test to determine the impact of the number of processes on memory pressure:

```
[-] $ snmpget localhost \
    'NET-SNMP-EXTEND-MIB::nsExtendResult."httpd_pids"' \
    UCD-SNMP-MIB::memAvailReal.0
NET-SNMP-EXTEND-MIB::nsExtendResult."httpd_pids" = INTEGER: 8
UCD-SNMP-MIB::memAvailReal.0 = INTEGER: 799664 kB
```

### 19.7.5.2. Extending Net-SNMP with Perl

Executing shell scripts using the `extend` directive is a fairly limited method for exposing custom application metrics over SNMP. The Net-SNMP Agent also provides an embedded Perl interface for exposing custom objects. The `net-snmp-perl` package in the Optional channel provides the `NetSNMP::agent` Perl module that is used to write embedded Perl plug-ins on Red Hat Enterprise Linux.
NOTE

Before subscribing to the Optional and Supplementary channels see the Scope of Coverage Details. If you decide to install packages from these channels, follow the steps documented in the article called How to access Optional and Supplementary channels, and -devel packages using Red Hat Subscription Manager (RHSM) on the Red Hat Customer Portal.

The NetSNMP::agent Perl module provides an agent object which is used to handle requests for a part of the agent's OID tree. The agent object's constructor has options for running the agent as a sub-agent of snmpd or a standalone agent. No arguments are necessary to create an embedded agent:

```perl
use NetSNMP::agent (':all');
my $agent = new NetSNMP::agent();
```

The agent object has a register method which is used to register a callback function with a particular OID. The register function takes a name, OID, and pointer to the callback function. The following example will register a callback function named hello_handler with the SNMP Agent which will handle requests under the OID .1.3.6.1.4.1.8072.9999.9999:

```perl
$agent->register("hello_world", ".1.3.6.1.4.1.8072.9999.9999", \&hello_handler);
```

NOTE

The OID .1.3.6.1.4.1.8072.9999.9999 (NET-SNMP-MIB::netSnmpPlaypen) is typically used for demonstration purposes only. If your organization does not already have a root OID, you can obtain one by contacting an ISO Name Registration Authority (ANSI in the United States).

The handler function will be called with four parameters, HANDLER, REGISTRATION_INFO, REQUEST_INFO, and REQUESTS. The REQUESTS parameter contains a list of requests in the current call and should be iterated over and populated with data. The request objects in the list have get and set methods which allow for manipulating the OID and value of the request. For example, the following call will set the value of a request object to the string “hello world”:

```perl
$request->setValue(ASN_OCTET_STR, "hello world");
```

The handler function should respond to two types of SNMP requests: the GET request and the GETNEXT request. The type of request is determined by calling the getMode method on the request_info object passed as the third parameter to the handler function. If the request is a GET request, the caller will expect the handler to set the value of the request object, depending on the OID of the request. If the request is a GETNEXT request, the caller will also expect the handler to set the OID of the request to the next available OID in the tree. This is illustrated in the following code example:

```perl
my $request;
my $string_value = "hello world";
my $integer_value = "8675309";
for($request = $requests; $request; $request = $request->next()) {
```
When `getMode` returns `MODE_GET`, the handler analyzes the value of the `getOID` call on the `request` object. The value of the `request` is set to either `string_value` if the OID ends in “1.0”, or set to `integer_value` if the OID ends in “1.1”. If the `getMode` returns `MODE_GETNEXT`, the handler determines whether the OID of the request is “1.0”, and then sets the OID and value for “1.1”. If the request is higher on the tree than “1.0”, the OID and value for “1.0” is set. This in effect returns the “next” value in the tree so that a program like `snmpwalk` can traverse the tree without prior knowledge of the structure.

The type of the variable is set using constants from `NetSNMP::ASN`. See the `perldoc` for `NetSNMP::ASN` for a full list of available constants.

The entire code listing for this example Perl plug-in is as follows:

```perl
#!/usr/bin/perl
use NetSNMP::agent (':all');
use NetSNMP::ASN qw(ASN_OCTET_STR ASN_INTEGER);

sub hello_handler { 
    my ($handler, $registration_info, $request_info, $requests) = @_; 
    my $request; 
    my $string_value = "hello world"; 
    my $integer_value = "8675309"; 

    for($request = $requests; $request; $request = $request->next()) { 
        my $oid = $request->getOID(); 
        if ($request_info->getMode() == MODE_GET) { 
            if ($oid == new NetSNMP::OID("1.3.6.1.4.1.8072.9999.9999.1.0")) { 
                $request->setValue(ASN_OCTET_STR, $string_value); 
            } 
            elsif ($oid == new NetSNMP::OID("1.3.6.1.4.1.8072.9999.9999.1.1")) { 
                $request->setValue(ASN_INTEGER, $integer_value); 
            } 
        } elsif ($request_info->getMode() == MODE_GETNEXT) { 
            if ($oid == new NetSNMP::OID("1.3.6.1.4.1.8072.9999.9999.1.0")) { 
                $request->setOID("1.3.6.1.4.1.8072.9999.9999.1.1"); 
                $request->setValue(ASN_INTEGER, $integer_value); 
            } elsif ($oid < new NetSNMP::OID("1.3.6.1.4.1.8072.9999.9999.1.0")) { 
                $request->setOID("1.3.6.1.4.1.8072.9999.9999.1.0"); 
                $request->setValue(ASN_OCTET_STR, $string_value); 
            } 
        } 
    }
}
```
To test the plug-in, copy the above program to `/usr/share/snmp/hello_world.pl` and add the following line to the `/etc/snmp/snmpd.conf` configuration file:

```perl
do "/usr/share/snmp/hello_world.pl"
```

The SNMP Agent Daemon will need to be restarted to load the new Perl plug-in. Once it has been restarted, an `snmpwalk` should return the new data:

```bash
$ snmpwalk localhost NET-SNMP-MIB::netSnmpPlaypen
NET-SNMP-MIB::netSnmpPlaypen.1.0 = STRING: "hello world"
NET-SNMP-MIB::netSnmpPlaypen.1.1 = INTEGER: 8675309
```

The `snmpget` should also be used to exercise the other mode of the handler:

```bash
$ snmpget localhost
NET-SNMP-MIB::netSnmpPlaypen.1.0
NET-SNMP-MIB::netSnmpPlaypen.1.1
NET-SNMP-MIB::netSnmpPlaypen.1.0 = STRING: "hello world"
NET-SNMP-MIB::netSnmpPlaypen.1.1 = INTEGER: 8675309
```

19.8. ADDITIONAL RESOURCES

To learn more about gathering system information, see the following resources.

19.8.1. Installed Documentation

- `lscpu(1)` – The manual page for the `lscpu` command.
- `lsusb(8)` – The manual page for the `lsusb` command.
- `findmnt(8)` – The manual page for the `findmnt` command.
- `blkid(8)` – The manual page for the `blkid` command.

- **du(1)** – The manual page for the `du` command.
- **lspci(8)** – The manual page for the `lspci` command.
- **snmpd(8)** – The manual page for the `snmpd` service.
- **snmpd.conf(5)** – The manual page for the `/etc/snmp/snmpd.conf` file containing full documentation of available configuration directives.
CHAPTER 20. OPENLMI

The Open Linux Management Infrastructure, commonly abbreviated as OpenLMI, is a common infrastructure for the management of Linux systems. It builds on top of existing tools and serves as an abstraction layer in order to hide much of the complexity of the underlying system from system administrators. OpenLMI is distributed with a set of services that can be accessed locally or remotely and provides multiple language bindings, standard APIs, and standard scripting interfaces that can be used to manage and monitor hardware, operating systems, and system services.

20.1. ABOUT OPENLMI

OpenLMI is designed to provide a common management interface to production servers running the Red Hat Enterprise Linux system on both physical and virtual machines. It consists of the following three components:

1. System management agents—these agents are installed on a managed system and implement an object model that is presented to a standard object broker. The initial agents implemented in OpenLMI include storage configuration and network configuration, but later work will address additional elements of system management. The system management agents are commonly referred to as Common Information Model providers or CIM providers.

2. A standard object broker—the object broker manages system management agents and provides an interface to them. The standard object broker is also known as a CIM Object Monitor or CIMOM.

3. Client applications and scripts—the client applications and scripts call the system management agents through the standard object broker.

The OpenLMI project complements existing management initiatives by providing a low-level interface that can be used by scripts or system management consoles. Interfaces distributed with OpenLMI include C, C++, Python, Java, and an interactive command line client, and all of them offer the same full access to the capabilities implemented in each agent. This ensures that you always have access to exactly the same capabilities no matter which programming interface you decide to use.

20.1.1. Main Features

The following are key benefits of installing and using OpenLMI on your system:

- OpenLMI provides a standard interface for configuration, management, and monitoring of your local and remote systems.

- It allows you to configure, manage, and monitor production servers running on both physical and virtual machines.

- It is distributed with a collection of CIM providers that allow you to configure, manage, and monitor storage devices and complex networks.

- It allows you to call system management functions from C, C++, Python, and Java programs, and includes LMIShell, which provides a command line interface.

- It is free software based on open industry standards.

20.1.2. Management Capabilities

Key capabilities of OpenLMI include the management of storage devices, networks, system services,
user accounts, hardware and software configuration, power management, and interaction with Active Directory. For a complete list of CIM providers that are distributed with Red Hat Enterprise Linux 7, see Table 20.1, “Available CIM Providers”.

### Table 20.1. Available CIM Providers

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openlmi-account</td>
<td>A CIM provider for managing user accounts.</td>
</tr>
<tr>
<td>openlmi-logicalfile</td>
<td>A CIM provider for reading files and directories.</td>
</tr>
<tr>
<td>openlmi-networking</td>
<td>A CIM provider for network management.</td>
</tr>
<tr>
<td>openlmi-powermanagement</td>
<td>A CIM provider for power management.</td>
</tr>
<tr>
<td>openlmi-service</td>
<td>A CIM provider for managing system services.</td>
</tr>
<tr>
<td>openlmi-storage</td>
<td>A CIM provider for storage management.</td>
</tr>
<tr>
<td>openlmi-fan</td>
<td>A CIM provider for controlling computer fans.</td>
</tr>
<tr>
<td>openlmi-hardware</td>
<td>A CIM provider for retrieving hardware information.</td>
</tr>
<tr>
<td>openlmi-realmd</td>
<td>A CIM provider for configuring realmd.</td>
</tr>
<tr>
<td>openlmi-software[a]</td>
<td>A CIM provider for software management.</td>
</tr>
</tbody>
</table>

[a] In Red Hat Enterprise Linux 7, the OpenLMI Software provider is included as a Technology Preview. This provider is fully functional, but has a known performance scaling issue where listing large numbers of software packages may consume excessive amount of memory and time. To work around this issue, adjust package searches to return as few packages as possible.

---

## 20.2. INSTALLING OPENLMI

OpenLMI is distributed as a collection of RPM packages that include the CIMOM, individual CIM providers, and client applications. This allows you distinguish between a managed and client system and install only those components you need.

### 20.2.1. Installing OpenLMI on a Managed System

A managed system is the system you intend to monitor and manage by using the OpenLMI client tools. To install OpenLMI on a managed system, complete the following steps:

1. Install the `tog-pegasus` package by typing the following at a shell prompt as `root`:

   ```bash
   yum install tog-pegasus
   ```

   This command installs the OpenPegasus CIMOM and all its dependencies to the system and creates a user account for the `pegasus` user.
2. Install required CIM providers by running the following command as *root*:

```
yum install openlmi-
    {storage, networking, service, account, powermanagement}
```

This command installs the CIM providers for storage, network, service, account, and power management. For a complete list of CIM providers distributed with Red Hat Enterprise Linux 7, see Table 20.1, “Available CIM Providers”.

3. Edit the `/etc/Pegasus/access.conf` configuration file to customize the list of users that are allowed to connect to the OpenPegasus CIMOM. By default, only the *pegasus* user is allowed to access the CIMOM both remotely and locally. To activate this user account, run the following command as *root* to set the user's password:

```
passwd pegasus
```

4. Start the OpenPegasus CIMOM by activating the `tog-pegasus.service` unit. To activate the `tog-pegasus.service` unit in the current session, type the following at a shell prompt as *root*:

```
systemctl start tog-pegasus.service
```

To configure the `tog-pegasus.service` unit to start automatically at boot time, type as *root*:

```
systemctl enable tog-pegasus.service
```

5. If you intend to interact with the managed system from a remote machine, enable TCP communication on port **5989** (`wbem-https`). To open this port in the current session, run the following command as *root*:

```
firewall-cmd --add-port 5989/tcp
```

To open port **5989** for TCP communication permanently, type as *root*:

```
firewall-cmd --permanent --add-port 5989/tcp
```

You can now connect to the managed system and interact with it by using the OpenLMI client tools as described in Section 20.4, “Using LMIShell”. If you intend to perform OpenLMI operations directly on the managed system, also complete the steps described in Section 20.2.2, “Installing OpenLMI on a Client System”.

### 20.2.2. Installing OpenLMI on a Client System

A *client system* is the system from which you intend to interact with the managed system. In a typical scenario, the client system and the managed system are installed on two separate machines, but you can also install the client tools on the managed system and interact with it directly.

To install OpenLMI on a client system, complete the following steps:

1. Install the `openlmi-tools` package by typing the following at a shell prompt as *root*:
yum install openlmi-tools

This command installs LMIShell, an interactive client and interpreter for accessing CIM objects provided by OpenPegasus, and all its dependencies to the system.

2. Configure SSL certificates for OpenPegasus as described in Section 20.3, “Configuring SSL Certificates for OpenPegasus”.

You can now use the LMIShell client to interact with the managed system as described in Section 20.4, “Using LMIShell”.

20.3. CONFIGURING SSL CERTIFICATES FOR OPENPEGASUS

OpenLMI uses the Web-Based Enterprise Management (WBEM) protocol that functions over an HTTP transport layer. Standard HTTP Basic authentication is performed in this protocol, which means that the user name and password are transmitted alongside the requests.

Configuring the OpenPegasus CIMOM to use HTTPS for communication is necessary to ensure secure authentication. A Secure Sockets Layer (SSL) or Transport Layer Security (TLS) certificate is required on the managed system to establish an encrypted channel.

There are two ways of managing SSL/TLS certificates on a system:

- Self-signed certificates require less infrastructure to use, but are more difficult to deploy to clients and manage securely.
- Authority-signed certificates are easier to deploy to clients once they are set up, but may require a greater initial investment.

When using an authority-signed certificate, it is necessary to configure a trusted certificate authority on the client systems. The authority can then be used for signing all of the managed systems' CIMOM certificates. Certificates can also be part of a certificate chain, so the certificate used for signing the managed systems' certificates may in turn be signed by another, higher authority (such as Verisign, CACert, RSA and many others).

The default certificate and trust store locations on the file system are listed in Table 20.2, “Certificate and Trust Store Locations”.

Table 20.2. Certificate and Trust Store Locations

<table>
<thead>
<tr>
<th>Configuration Option</th>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslCertificateFilePath</td>
<td>/etc/Pegasus/server.pem</td>
<td>Public certificate of the CIMOM.</td>
</tr>
<tr>
<td>sslKeyFilePath</td>
<td>/etc/Pegasus/file.pem</td>
<td>Private key known only to the CIMOM.</td>
</tr>
<tr>
<td>sslTrustStore</td>
<td>/etc/Pegasus/client.pem</td>
<td>The file or directory providing the list of trusted certificate authorities.</td>
</tr>
</tbody>
</table>
IMPORTANT

If you modify any of the files mentioned in Table 20.2, “Certificate and Trust Store Locations”, restart the tog-pegasus service to make sure it recognizes the new certificates. To restart the service, type the following at a shell prompt as root:

```bash
systemctl restart tog-pegasus.service
```

For more information on how to manage system services in Red Hat Enterprise Linux 7, see Chapter 9, Managing Services with systemd.

20.3.1. Managing Self-signed Certificates

A self-signed certificate uses its own private key to sign itself and it is not connected to any chain of trust. On a managed system, if certificates have not been provided by the administrator prior to the first time that the tog-pegasus service is started, a set of self-signed certificates will be automatically generated using the system's primary host name as the certificate subject.

IMPORTANT

The automatically generated self-signed certificates are valid by default for 10 years, but they have no automatic-renewal capability. Any modification to these certificates will require manually creating new certificates following guidelines provided by the OpenSSL or Mozilla NSS documentation on the subject.

To configure client systems to trust the self-signed certificate, complete the following steps:

1. Copy the `/etc/Pegasus/server.pem` certificate from the managed system to the `/etc/pki/ca-trust/source/anchors/` directory on the client system. To do so, type the following at a shell prompt as root:

```bash
scp root@hostname:/etc/Pegasus/server.pem /etc/pki/ca-trust/source/anchors/pegasus-hostname.pem
```

Replace `hostname` with the host name of the managed system. Note that this command only works if the sshd service is running on the managed system and is configured to allow the root user to log in to the system over the SSH protocol. For more information on how to install and configure the sshd service and use the scp command to transfer files over the SSH protocol, see Chapter 11, OpenSSH.

2. Verify the integrity of the certificate on the client system by comparing its check sum with the check sum of the original file. To calculate the check sum of the `/etc/Pegasus/server.pem` file on the managed system, run the following command as root on that system:

```bash
sha1sum /etc/Pegasus/server.pem
```

To calculate the check sum of the `/etc/pki/ca-trust/source/anchors/pegasus-hostname.pem` file on the client system, run the following command on this system:

```bash
sha1sum /etc/pki/ca-trust/source/anchors/pegasus-hostname.pem
```
Replace hostname with the host name of the managed system.

3. Update the trust store on the client system by running the following command as root:

   ```
   update-ca-trust extract
   ```

20.3.2. Managing Authority-signed Certificates with Identity Management (Recommended)

The Identity Management feature of Red Hat Enterprise Linux provides a domain controller which simplifies the management of SSL certificates within systems joined to the domain. Among others, the Identity Management server provides an embedded Certificate Authority. See the Red Hat Enterprise Linux 7 Linux Domain Identity, Authentication, and Policy Guide or the FreeIPA documentation for information on how to join the client and managed systems to the domain.

It is necessary to register the managed system to Identity Management; for client systems the registration is optional.

The following steps are required on the managed system:

1. Install the ipa-client package and register the system to Identity Management as described in the Red Hat Enterprise Linux 7 Linux Domain Identity, Authentication, and Policy Guide.

2. Copy the Identity Management signing certificate to the trusted store by typing the following command as root:

   ```
   cp /etc/ipa/ca.crt /etc/pki/ca-trust/source/anchors/ipa.crt
   ```

3. Update the trust store by running the following command as root:

   ```
   update-ca-trust extract
   ```

4. Register Pegasus as a service in the Identity Management domain by running the following command as a privileged domain user:

   ```
   ipa service-add CIMOM/hostname
   ```

   Replace hostname with the host name of the managed system.

   This command can be run from any system in the Identity Management domain that has the ipa-admintools package installed. It creates a service entry in Identity Management that can be used to generate signed SSL certificates.

5. Back up the PEM files located in the /etc/Pegasus/ directory (recommended).

6. Retrieve the signed certificate by running the following command as root:

   ```
   ipa-getcert request -f /etc/Pegasus/server.pem -k /etc/Pegasus/file.pem -N CN=hostname -K CIMOM/hostname
   ```

   Replace hostname with the host name of the managed system.
The certificate and key files are now kept in proper locations. The certmonger daemon installed on the managed system by the `ipa-client-install` script ensures that the certificate is kept up-to-date and renewed as necessary.

For more information, see the Red Hat Enterprise Linux 7 Linux Domain Identity, Authentication, and Policy Guide.

To register the client system and update the trust store, follow the steps below.

1. Install the `ipa-client` package and register the system to Identity Management as described in the Red Hat Enterprise Linux 7 Linux Domain Identity, Authentication, and Policy Guide.

2. Copy the Identity Management signing certificate to the trusted store by typing the following command as `root`:

   ```
   cp /etc/ipa/ca.crt /etc/pki/ca-trust/source/anchors/ipa.crt
   ```

3. Update the trust store by running the following command as `root`:

   ```
   update-ca-trust extract
   ```

If the client system is not meant to be registered in Identity Management, complete the following steps to update the trust store.

1. Copy the `/etc/ipa/ca.crt` file securely from any other system joined to the same Identity Management domain to the trusted store `/etc/pki/ca-trust/source/anchors/` directory as `root`.

2. Update the trust store by running the following command as `root`:

   ```
   update-ca-trust extract
   ```

### 20.3.3. Managing Authority-signed Certificates Manually

Managing authority-signed certificates with other mechanisms than Identity Management requires more manual configuration.

It is necessary to ensure that all of the clients trust the certificate of the authority that will be signing the managed system certificates:

- If a certificate authority is trusted by default, it is not necessary to perform any particular steps to accomplish this.

- If the certificate authority is not trusted by default, the certificate has to be imported on the client and managed systems.

  1. Copy the certificate to the trusted store by typing the following command as `root`:

     ```
     cp /path/to/ca.crt /etc/pki/ca-trust/source/anchors/ca.crt
     ```

  2. Update the trust store by running the following command as `root`:

     ```
     update-ca-trust extract
     ```
On the managed system, complete the following steps:

1. Create a new SSL configuration file `/etc/Pegasus/ssl.cnf` to store information about the certificate. The contents of this file must be similar to the following example:

```
[ req ]
distinguished_name = req_distinguished_name
prompt = no
[ req_distinguished_name ]
C = US
ST = Massachusetts
L = Westford
O = Fedora
OU = Fedora OpenLMI
CN = hostname
```

Replace `hostname` with the fully qualified domain name of the managed system.

2. Generate a private key on the managed system by using the following command as root:

```
openssl genrsa -out /etc/Pegasus/file.pem 1024
```

3. Generate a certificate signing request (CSR) by running this command as root:

```
openssl req -config /etc/Pegasus/ssl.cnf -new -key /etc/Pegasus/file.pem -out /etc/Pegasus/server.csr
```

4. Send the `/etc/Pegasus/server.csr` file to the certificate authority for signing. The detailed procedure of submitting the file depends on the particular certificate authority.

5. When the signed certificate is received from the certificate authority, save it as `/etc/Pegasus/server.pem`.

6. Copy the certificate of the trusted authority to the Pegasus trust store to make sure that Pegasus is capable of trusting its own certificate by running as root:

```
cp /path/to/ca.crt /etc/Pegasus/client.pem
```

After accomplishing all the described steps, the clients that trust the signing authority are able to successfully communicate with the managed server's CIMOM.

**IMPORTANT**

Unlike the Identity Management solution, if the certificate expires and needs to be renewed, all of the described manual steps have to be carried out again. It is recommended to renew the certificates before they expire.

## 20.4. USING LMISHELL

LMIShell is an interactive client and non-interactive interpreter that can be used to access CIM objects provided by the OpenPegasus CIMOM. It is based on the Python interpreter, but also implements additional functions and classes for interacting with CIM objects.
20.4.1. Starting, Using, and Exiting LMIShell

Similarly to the Python interpreter, you can use LMIShell either as an interactive client, or as a non-interactive interpreter for LMIShell scripts.

Starting LMIShell in Interactive Mode
To start the LMIShell interpreter in interactive mode, run the `lmishell` command with no additional arguments:

```
> lmishell
```

By default, when LMIShell attempts to establish a connection with a CIMOM, it validates the server-side certificate against the Certification Authorities trust store. To disable this validation, run the `lmishell` command with the `--noverify` or `-n` command line option:

```
> lmishell --noverify
```

Using Tab Completion
When running in interactive mode, the LMIShell interpreter allows you press the Tab key to complete basic programming structures and CIM objects, including namespaces, classes, methods, and object properties.

Browsing History
By default, LMIShell stores all commands you type at the interactive prompt in the `~/.lmishell_history` file. This allows you to browse the command history and re-use already entered lines in interactive mode without the need to type them at the prompt again. To move backward in the command history, press the Up Arrow key or the Ctrl+p key combination. To move forward in the command history, press the Down Arrow key or the Ctrl+n key combination.

LMIShell also supports an incremental reverse search. To look for a particular line in the command history, press Ctrl+r and start typing any part of the command. For example:

```
> (reverse-i-search)`connect`: c = connect("server.example.com", "pegasus")
```

To clear the command history, use the `clear_history()` function as follows:

```
> clear_history()
```

You can configure the number of lines that are stored in the command history by changing the value of the `history_length` option in the `~/.lmishellrc` configuration file. In addition, you can change the location of the history file by changing the value of the `history_file` option in this configuration file. For example, to set the location of the history file to `~/.lmishell_history` and configure LMIShell to store the maximum of 1000 lines in it, add the following lines to the `~/.lmishellrc` file:

```
> history_file = "~/.lmishell_history"
> history_length = 1000
```

Handling Exceptions
By default, the LMIShell interpreter handles all exceptions and uses return values. To disable this behavior in order to handle all exceptions in the code, use the `use_exceptions()` function as follows:

```
> use_exceptions()
```
use_exceptions()

To re-enable the automatic exception handling, use:

use_exception(False)

You can permanently disable the exception handling by changing the value of the use_exceptions option in the ~/.lmishellrc configuration file to True:

use_exceptions = True

Configuring a Temporary Cache
With the default configuration, LMIShell connection objects use a temporary cache for storing CIM class names and CIM classes in order to reduce network communication. To clear this temporary cache, use the clear_cache() method as follows:

object_name.clear_cache()

Replace object_name with the name of a connection object.

To disable the temporary cache for a particular connection object, use the use_cache() method as follows:

object_name.use_cache(False)

To enable it again, use:

object_name.use_cache(True)

You can permanently disable the temporary cache for connection objects by changing the value of the use_cache option in the ~/.lmishellrc configuration file to False:

use_cache = False

Exiting LMIShell
To terminate the LMIShell interpreter and return to the shell prompt, press the Ctrl+d key combination or issue the quit() function as follows:

> quit()
~]$ 

Running an LMIShell Script
To run an LMIShell script, run the lmishell command as follows:

lmishell file_name

Replace file_name with the name of the script. To inspect an LMIShell script after its execution, also specify the --interact or -i command line option:

lmishell --interact file_name
The preferred file extension of LMIShell scripts is `.lmi`.

## 20.4.2. Connecting to a CIMOM

LMIShell allows you to connect to a CIMOM that is running either locally on the same system, or on a remote machine accessible over the network.

### Connecting to a Remote CIMOM

To access CIM objects provided by a remote CIMOM, create a connection object by using the `connect()` function as follows:

```python
connect(host_name, user_name[, password])
```

Replace `host_name` with the host name of the managed system, `user_name` with the name of a user that is allowed to connect to the OpenPegasus CIMOM running on that system, and `password` with the user's password. If the password is omitted, LMIShell prompts the user to enter it. The function returns an `LMIConnection` object.

**Example 20.1. Connecting to a Remote CIMOM**

To connect to the OpenPegasus CIMOM running on `server.example.com` as user `pegasus`, type the following at the interactive prompt:

```bash
> c = connect("server.example.com", "pegasus")
prompt:>
```

### Connecting to a Local CIMOM

LMIShell allows you to connect to a local CIMOM by using a Unix socket. For this type of connection, you must run the LMIShell interpreter as the root user and the `/var/run/tog-pegasus/cimxml.socket` socket must exist.

To access CIM objects provided by a local CIMOM, create a connection object by using the `connect()` function as follows:

```python
connect(host_name)
```

Replace `host_name` with `localhost`, `127.0.0.1`, or `::1`. The function returns an `LMIConnection` object or `None`.

**Example 20.2. Connecting to a Local CIMOM**

To connect to the OpenPegasus CIMOM running on `localhost` as the root user, type the following at the interactive prompt:

```bash
> c = connect("localhost")
> 
```

### Verifying a Connection to a CIMOM

...
The `connect()` function returns either an `LMIMConnection` object, or `None` if the connection could not be established. In addition, when the `connect()` function fails to establish a connection, it prints an error message to standard error output.

To verify that a connection to a CIMOM has been established successfully, use the `isinstance()` function as follows:

```python
isinstance(object_name, LMIMConnection)
```

Replace `object_name` with the name of the connection object. This function returns `True` if `object_name` is an `LMIMConnection` object, or `False` otherwise.

**Example 20.3. Verifying a Connection to a CIMOM**

To verify that the `c` variable created in Example 20.1, “Connecting to a Remote CIMOM” contains an `LMIMConnection` object, type the following at the interactive prompt:

```bash
> isinstance(c, LMIMConnection)
True
>
```

Alternatively, you can verify that `c` is not `None`:

```bash
> c is None
False
>
```

### 20.4.3. Working with Namespaces

LMIShell namespaces provide a natural means of organizing available classes and serve as a hierarchic access point to other namespaces and classes. The `root` namespace is the first entry point of a connection object.

#### Listing Available Namespaces

To list all available namespaces, use the `print_namespaces()` method as follows:

```python
object_name.print_namespaces()
```

Replace `object_name` with the name of the object to inspect. This method prints available namespaces to standard output.

To get a list of available namespaces, access the object attribute `namespaces`:

```python
object_name.namespaces
```

This returns a list of strings.

**Example 20.4. Listing Available Namespaces**
To inspect the root namespace object of the connection object created in Example 20.1, “Connecting to a Remote CIMOM” and list all available namespaces, type the following at the interactive prompt:

```python
> c.root.print_namespaces()
cimv2 interop PG_InterOp PG_Internal
```

To assign a list of these namespaces to a variable named root_namespaces, type:

```python
> root_namespaces = c.root.namespaces
```

### Accessing Namespace Objects

To access a particular namespace object, use the following syntax:

```python
object_name.namespace_name
```

Replace `object_name` with the name of the object to inspect and `namespace_name` with the name of the namespace to access. This returns an LMINamespace object.

### Example 20.5. Accessing Namespace Objects

To access the cimv2 namespace of the connection object created in Example 20.1, “Connecting to a Remote CIMOM” and assign it to a variable named `ns`, type the following at the interactive prompt:

```python
> ns = c.root.cimv2
```

### 20.4.4. Working with Classes

LMIShell classes represent classes provided by a CIMOM. You can access and list their properties, methods, instances, instance names, and ValueMap properties, print their documentation strings, and create new instances and instance names.

#### Listing Available Classes

To list all available classes in a particular namespace, use the `print_classes()` method as follows:

```python
namespace_object.print_classes()
```

Replace `namespace_object` with the namespace object to inspect. This method prints available classes to standard output.

To get a list of available classes, use the `classes()` method:

```python
namespace_object.classes()
```
This method returns a list of strings.

**Example 20.6. Listing Available Classes**

To inspect the ns namespace object created in Example 20.5, “Accessing Namespace Objects” and list all available classes, type the following at the interactive prompt:

```
> ns.print_classes()
CIM_CollectionInSystem
CIM_ConcreteIdentity
CIM_ControlledBy
CIM_DeviceSAPImplementation
CIM_MemberOfStatusCollection
...
```

To assign a list of these classes to a variable named cimv2_classes, type:

```
> cimv2_classes = ns.classes()
```

**Accessing Class Objects**

To access a particular class object that is provided by the CIMOM, use the following syntax:

```
namespace_object.class_name
```

Replace `namespace_object` with the name of the namespace object to inspect and `class_name` with the name of the class to access.

**Example 20.7. Accessing Class Objects**

To access the LMI_IPNetworkConnection class of the ns namespace object created in Example 20.5, “Accessing Namespace Objects” and assign it to a variable named cls, type the following at the interactive prompt:

```
> cls = ns.LMI_IPNetworkConnection
```

**Examining Class Objects**

All class objects store information about their name and the namespace they belong to, as well as detailed class documentation. To get the name of a particular class object, use the following syntax:

```
class_object.classname
```

Replace `class_object` with the name of the class object to inspect. This returns a string representation of the object name.

To get information about the namespace a class object belongs to, use:

```
class_object.namespace
```
This returns a string representation of the namespace.

To display detailed class documentation, use the `doc()` method as follows:

```python
class_object.doc()
```

**Example 20.8. Examining Class Objects**

To inspect the `cls` class object created in Example 20.7, “Accessing Class Objects” and display its name and corresponding namespace, type the following at the interactive prompt:

```python
> cls.classname
'LMI_IPNetworkConnection'
> cls.namespace
'root/cimv2'
>
```

To access class documentation, type:

```python
> cls.doc()
Class: LMI_IPNetworkConnection
   SuperClass: CIM_IPNetworkConnection
   [qualifier] string UMLPackagePath: 'CIM::Network::IP'
      ...
```

**Listing Available Methods**

To list all available methods of a particular class object, use the `print_methods()` method as follows:

```python
class_object.print_methods()
```

Replace `class_object` with the name of the class object to inspect. This method prints available methods to standard output.

To get a list of available methods, use the `methods()` method:

```python
class_object.methods()
```

This method returns a list of strings.

**Example 20.9. Listing Available Methods**

To inspect the `cls` class object created in Example 20.7, “Accessing Class Objects” and list all available methods, type the following at the interactive prompt:

```python
> cls.print_methods()
RequestStateChange
>
```

To assign a list of these methods to a variable named `service_methods`, type:
Listing Available Properties
To list all available properties of a particular class object, use the `print_properties()` method as follows:

```python
class_object.print_properties()
```

Replace `class_object` with the name of the class object to inspect. This method prints available properties to standard output.

To get a list of available properties, use the `properties()` method:

```python
class_object.properties()
```

This method returns a list of strings.

Example 20.10. Listing Available Properties
To inspect the `cls` class object created in Example 20.7, “Accessing Class Objects” and list all available properties, type the following at the interactive prompt:

```sql
> cls.print_properties()
RequestedState
HealthState
StatusDescriptions
TransitioningToState
Generation
...
>
```

To assign a list of these classes to a variable named `service_properties`, type:

```sql
> service_properties = cls.properties()
>
```

Listing and Viewing ValueMap Properties
CIM classes may contain `ValueMap properties` in their Managed Object Format (MOF) definition. ValueMap properties contain constant values, which may be useful when calling methods or checking returned values.

To list all available ValueMap properties of a particular class object, use the `print_valuemap_properties()` method as follows:

```python
class_object.print_valuemap_properties()
```

Replace `class_object` with the name of the class object to inspect. This method prints available ValueMap properties to standard output:

To get a list of available ValueMap properties, use the `valuemap_properties()` method:
class_object.valuemap_properties()

This method returns a list of strings.

Example 20.11. Listing ValueMap Properties

To inspect the cls class object created in Example 20.7, “Accessing Class Objects” and list all available ValueMap properties, type the following at the interactive prompt:

```python
> cls.print_valuemap_properties()
RequestedState
HealthState
TransitioningToState
DetailedStatus
OperationalStatus
...
>
```

To assign a list of these ValueMap properties to a variable named `service_valuemap_properties`, type:

```python
> service_valuemap_properties = cls.valuemap_properties()
>
```

To access a particular ValueMap property, use the following syntax:

```python
class_object.valuemap_propertyValues
```

Replace `valuemap_property` with the name of the ValueMap property to access.

To list all available constant values, use the `print_values()` method as follows:

```python
class_object.valuemap_propertyValues.print_values()
```

This method prints available named constant values to standard output. You can also get a list of available constant values by using the `values()` method:

```python
class_object.valuemap_propertyValues.values()
```

This method returns a list of strings.

Example 20.12. Accessing ValueMap Properties

Example 20.11, “Listing ValueMap Properties” mentions a ValueMap property named `RequestedState`. To inspect this property and list available constant values, type the following at the interactive prompt:

```python
> cls.RequestedStateValues.print_values()
Reset
NoChange
NotApplicable
Quiesce
```
To assign a list of these constant values to a variable named `requested_state_values`, type:

```python
> requested_state_values = cls.RequestedStateValues.values()
```

To access a particular constant value, use the following syntax:

```python
class_object.valuemap_propertyValues.constant_value_name
```

Replace `constant_value_name` with the name of the constant value. Alternatively, you can use the `value()` method as follows:

```python
class_object.valuemap_propertyValues.value("constant_value_name")
```

To determine the name of a particular constant value, use the `value_name()` method:

```python
class_object.valuemap_propertyValues.value_name("constant_value")
```

This method returns a string.

**Example 20.13. Accessing Constant Values**

**Example 20.12, “Accessing ValueMap Properties”** shows that the `RequestedState` property provides a constant value named `Reset`. To access this named constant value, type the following at the interactive prompt:

```python
> cls.RequestedStateValues.Reset
11
> cls.RequestedStateValues.value("Reset")
11
```

To determine the name of this constant value, type:

```python
> cls.RequestedStateValues.value_name(11)
u'Reset'
```

**Fetching a CIMClass Object**

Many class methods do not require access to a CIMClass object, which is why LMI Shell only fetches this object from the CIMOM when a called method actually needs it. To fetch the CIMObject manually, use the `fetch()` method as follows:

```python
class_object.fetch()
```
Replace \texttt{class\_object} with the name of the class object. Note that methods that require access to a \texttt{CIMClass} object fetch it automatically.

### 20.4.5. Working with Instances

LMIShell instances represent instances provided by a CIMOM. You can get and set their properties, list and call their methods, print their documentation strings, get a list of associated or association objects, push modified objects to the CIMOM, and delete individual instances from the CIMOM.

**Accessing Instances**

To get a list of all available instances of a particular class object, use the \texttt{instances()} method as follows:

\begin{verbatim}
class\_object\_.instances()
\end{verbatim}

Replace \texttt{class\_object} with the name of the class object to inspect. This method returns a list of \texttt{LMIInstance} objects.

To access the first instance of a class object, use the \texttt{first\_instance()} method:

\begin{verbatim}
class\_object\_.first\_instance()
\end{verbatim}

This method returns an \texttt{LMIInstance} object.

In addition to listing all instances or returning the first one, both \texttt{instances()} and \texttt{first\_instance()} support an optional argument to allow you to filter the results:

\begin{verbatim}
class\_object\_.instances(criteria)
\end{verbatim}

\begin{verbatim}
class\_object\_.first\_instance(criteria)
\end{verbatim}

Replace \texttt{criteria} with a dictionary consisting of key-value pairs, where keys represent instance properties and values represent required values of these properties.

**Example 20.14. Accessing Instances**

To find the first instance of the \texttt{cls} class object created in Example 20.7, “Accessing Class Objects” that has the \texttt{ElementName} property equal to \texttt{eth0} and assign it to a variable named \texttt{device}, type the following at the interactive prompt:

\begin{verbatim}
> device = cls.first\_instance({"ElementName": "eth0"})
\end{verbatim}

**Examining Instances**

All instance objects store information about their class name and the namespace they belong to, as well as detailed documentation about their properties and values. In addition, instance objects allow you to retrieve a unique identification object.

To get the class name of a particular instance object, use the following syntax:

\begin{verbatim}
instance\_object\_.classname
\end{verbatim}
Replace *instance_object* with the name of the instance object to inspect. This returns a string representation of the class name.

To get information about the namespace an instance object belongs to, use:

*instance_object*.namespace

This returns a string representation of the namespace.

To retrieve a unique identification object for an instance object, use:

*instance_object*.path

This returns an `LMIInstanceName` object.

Finally, to display detailed documentation, use the `doc()` method as follows:

*instance_object*.doc()

**Example 20.15. Examining Instances**

To inspect the `device` instance object created in Example 20.14, “Accessing Instances” and display its class name and the corresponding namespace, type the following at the interactive prompt:

```
> device.classname
u'LMI_IPNetworkConnection'
> device.namespace
'root/cimv2'
>
```

To access instance object documentation, type:

```
> device.doc()
Instance of LMI_IPNetworkConnection
    [property] uint16 RequestedState = '12'
    [property] uint16 HealthState
        [property array] string [] StatusDescriptions
    ...
```

**Creating New Instances**

Certain CIM providers allow you to create new instances of specific classes objects. To create a new instance of a class object, use the `create_instance()` method as follows:

*class_object*.create_instance(*properties*)

Replace *class_object* with the name of the class object and *properties* with a dictionary that consists of key-value pairs, where keys represent instance properties and values represent property values. This method returns an `LMIInstance` object.
Example 20.16. Creating New Instances

The LMI_Group class represents system groups and the LMI_Account class represents user accounts on the managed system. To use the ns namespace object created in Example 20.5, “Accessing Namespace Objects”, create instances of these two classes for the system group named pegasus and the user named lmishell-user, and assign them to variables named group and user, type the following at the interactive prompt:

```
> group = ns.LMI_Group.first_instance("Name" : "pegasus")
> user = ns.LMI_Account.first_instance("Name" : "lmishell-user")
```

To get an instance of the LMI_Identity class for the lmishell-user user, type:

```
> identity = user.first_associator(ResultClass="LMI_Identity")
```

The LMI_MemberOfGroup class represents system group membership. To use the LMI_MemberOfGroup class to add the lmishell-user to the pegasus group, create a new instance of this class as follows:

```
> ns.LMI_MemberOfGroup.create_instance({
...   "Member" : identity.path,
...   "Collection" : group.path})
LMIInstance(classname="LMI_MemberOfGroup", ...)
```

Deleting Individual Instances

To delete a particular instance from the CIMOM, use the delete() method as follows:

```
instance_object.delete()
```

Replace instance_object with the name of the instance object to delete. This method returns a boolean. Note that after deleting an instance, its properties and methods become inaccessible.

Example 20.17. Deleting Individual Instances

The LMI_Account class represents user accounts on the managed system. To use the ns namespace object created in Example 20.5, “Accessing Namespace Objects”, create an instance of the LMI_Account class for the user named lmishell-user, and assign it to a variable named user, type the following at the interactive prompt:

```
> user = ns.LMI_Account.first_instance("Name" : "lmishell-user")
```

To delete this instance and remove the lmishell-user from the system, type:

```
> user.delete()
True
```
Listing and Accessing Available Properties

To list all available properties of a particular instance object, use the `print_properties()` method as follows:

```
instance_object.print_properties()
```

Replace `instance_object` with the name of the instance object to inspect. This method prints available properties to standard output.

To get a list of available properties, use the `properties()` method:

```
instance_object.properties()
```

This method returns a list of strings.

**Example 20.18. Listing Available Properties**

To inspect the `device` instance object created in Example 20.14, “Accessing Instances” and list all available properties, type the following at the interactive prompt:

```
> device.print_properties()
RequestedState
HealthState
StatusDescriptions
TransitioningToState
Generation
...
>
```

To assign a list of these properties to a variable named `device_properties`, type:

```
> device_properties = device.properties()
>
```

To get the current value of a particular property, use the following syntax:

```
instance_object.property_name
```

Replace `property_name` with the name of the property to access.

To modify the value of a particular property, assign a value to it as follows:

```
instance_object.property_name = value
```

Replace `value` with the new value of the property. Note that in order to propagate the change to the CIMOM, you must also execute the `push()` method:

```
instance_object.push()
```

This method returns a three-item tuple consisting of a return value, return value parameters, and an error string.
Example 20.19. Accessing Individual Properties

To inspect the device instance object created in Example 20.14, “Accessing Instances” and display the value of the property named SystemName, type the following at the interactive prompt:

```
> device.SystemName
u'server.example.com'
>
```

Listing and Using Available Methods

To list all available methods of a particular instance object, use the `print_methods()` method as follows:

```
instance_object.print_methods()
```

Replace `instance_object` with the name of the instance object to inspect. This method prints available methods to standard output.

To get a list of available methods, use the `method()` method:

```
instance_object.methods()
```

This method returns a list of strings.

Example 20.20. Listing Available Methods

To inspect the device instance object created in Example 20.14, “Accessing Instances” and list all available methods, type the following at the interactive prompt:

```
> device.print_methods()
RequestStateChange
>
```

To assign a list of these methods to a variable named `network_device_methods`, type:

```
> network_device_methods = device.methods()
>
```

To call a particular method, use the following syntax:

```
instance_object.method_name(
    parameter=value,
    ...
)
```

Replace `instance_object` with the name of the instance object to use, `method_name` with the name of the method to call, `parameter` with the name of the parameter to set, and `value` with the value of this parameter. Methods return a three-item tuple consisting of a return value, return value parameters, and an error string.
IMPORTANT

LMInstance objects do not automatically refresh their contents (properties, methods, qualifiers, and so on). To do so, use the refresh() method as described below.

Example 20.21. Using Methods

The PG_ComputerSystem class represents the system. To create an instance of this class by using the ns namespace object created in Example 20.5, “Accessing Namespace Objects” and assign it to a variable named sys, type the following at the interactive prompt:

```python
> sys = ns.PG_ComputerSystem.first_instance()
```

The LMI_AccountManagementService class implements methods that allow you to manage users and groups in the system. To create an instance of this class and assign it to a variable named acc, type:

```python
> acc = ns.LMI_AccountManagementService.first_instance()
```

To create a new user named lmishell-user in the system, use the CreateAccount() method as follows:

```python
> acc.CreateAccount(Name="lmishell-user", System=sys)
LMIReturnValue(rval=0, rparams=NocaseDict({u'Account':
LMIInstanceName(classname="LMI_Account"...), u'Identities':
[LMIInstanceName(classname="LMI_Identity"...),
LMIInstanceName(classname="LMI_Identity"...)]}), errorstr='')
```

LMI Shell support synchronous method calls: when you use a synchronous method, LMI Shell waits for the corresponding Job object to change its state to "finished" and then returns the return parameters of this job. LMI Shell is able to perform a synchronous method call if the given method returns an object of one of the following classes:

- LMI_StorageJob
- LMI_SoftwareInstallationJob
- LMI_NetworkJob

LMI Shell first tries to use indications as the waiting method. If it fails, it uses a polling method instead.

To perform a synchronous method call, use the following syntax:

```python
instance_object.Syncmethod_name( parameter=value,
...)
```

Replace instance_object with the name of the instance object to use, method_name with the name of the method to call, parameter with the name of the parameter to set, and value with the value of this parameter. All synchronous methods have the Sync prefix in their name and return a three-item tuple
consisting of the job's return value, job's return value parameters, and job's error string.

You can also force LMIShell to use only polling method. To do so, specify the PreferPolling parameter as follows:

```python
instance_object.Syncmethod_name(
    PreferPolling=True
    parameter=value,
    ...)
```

Listing and Viewing ValueMap Parameters

CIM methods may contain ValueMap parameters in their Managed Object Format (MOF) definition. ValueMap parameters contain constant values.

To list all available ValueMap parameters of a particular method, use the `print_valuemap_parameters()` method as follows:

```python
instance_object.method_name.print_valuemap_parameters()
```

Replace `instance_object` with the name of the instance object and `method_name` with the name of the method to inspect. This method prints available ValueMap parameters to standard output.

To get a list of available ValueMap parameters, use the `valuemap_parameters()` method:

```python
instance_object.method_name.valuemap_parameters()
```

This method returns a list of strings.

**Example 20.22. Listing ValueMap Parameters**

To inspect the `acc` instance object created in Example 20.21, “Using Methods” and list all available ValueMap parameters of the `CreateAccount()` method, type the following at the interactive prompt:

```bash
> acc.CreateAccount.print_valuemap_parameters()
CreateAccount
>
```

To assign a list of these ValueMap parameters to a variable named `create_account_parameters`, type:

```bash
> create_account_parameters = acc.CreateAccount.valuemap_parameters()
>
```

To access a particular ValueMap parameter, use the following syntax:

```python
instance_object.method_name.valuemap_parameterValues
```

Replace `valuemap_parameter` with the name of the ValueMap parameter to access.

To list all available constant values, use the `print_values()` method as follows:

```python
```
instance_object.method_name.valuemap_parameterValues.print_values()

This method prints available named constant values to standard output. You can also get a list of available constant values by using the values() method:

instance_object.method_name.valuemap_parameterValues.values()

This method returns a list of strings.

**Example 20.23. Accessing ValueMap Parameters**

Example 20.22, “Listing ValueMap Parameters” mentions a ValueMap parameter named CreateAccount. To inspect this parameter and list available constant values, type the following at the interactive prompt:

```
> acc.CreateAccount.CreateAccountValues.print_values()
Operationunsupported
Failed
Unabletopasswordusercreated
Subtitlecreatehomedirectoryusercreatedandpasswordset
Operationcompletedsuccessfully
>
```

To assign a list of these constant values to a variable named create_account_values, type:

```
> create_account_values = acc.CreateAccount.CreateAccountValues.values()
>
```

To access a particular constant value, use the following syntax:

```
instance_object.method_name.valuemap_parameterValues.constant_value_name
```

Replace constant_value_name with the name of the constant value. Alternatively, you can use the value() method as follows:

```
instance_object.method_name.valuemap_parameterValues.value("constant_value_name")
```

To determine the name of a particular constant value, use the value_name() method:

```
instance_object.method_name.valuemap_parameterValues.value_name("constant_value")
```

This method returns a string.

**Example 20.24. Accessing Constant Values**

Example 20.23, “Accessing ValueMap Parameters” shows that the CreateAccount ValueMap parameter provides a constant value named Failed. To access this named constant value, type the following at the interactive prompt:
To determine the name of this constant value, type:

```python
acc.CreateAccount.CreateAccountValues.value_name(2)
```

To determine the name of this constant value, type:

```python
u'Failed'
```

**Refreshing Instance Objects**

Local objects used by LMIShell, which represent CIM objects at CIMOM side, can get outdated, if such objects change while working with LMIShell's ones. To update the properties and methods of a particular instance object, use the `refresh()` method as follows:

```python
instance_object.refresh()
```

Replace `instance_object` with the name of the object to refresh. This method returns a three-item tuple consisting of a return value, return value parameter, and an error string.

**Example 20.25. Refreshing Instance Objects**

To update the properties and methods of the `device` instance object created in Example 20.14, "Accessing Instances", type the following at the interactive prompt:

```python
device.refresh()
```

```python
LMIReturnValue(rval=True, rparams=NocaseDict({}), errorstr='')
```

**Displaying MOF Representation**

To display the Managed Object Format (MOF) representation of an instance object, use the `tomof()` method as follows:

```python
instance_object.tomof()
```

Replace `instance_object` with the name of the instance object to inspect. This method prints the MOF representation of the object to standard output.

**Example 20.26. Displaying MOF Representation**

To display the MOF representation of the `device` instance object created in Example 20.14, "Accessing Instances", type the following at the interactive prompt:

```python
device.tomof()
```

```python
instance of LMI_IPNetworkConnection {
    RequestedState = 12;
    HealthState = NULL;
}
20.4.6. Working with Instance Names

LMIShell instance names are objects that hold a set of primary keys and their values. This type of an object exactly identifies an instance.

Accessing Instance Names

CIMInstance objects are identified by CIMInstanceName objects. To get a list of all available instance name objects, use the instance_names() method as follows:

```python
class_object.instance_names()
```

Replace `class_object` with the name of the class object to inspect. This method returns a list of LMIInstanceName objects.

To access the first instance name object of a class object, use the first_instance_name() method:

```python
class_object.first_instance_name()
```

This method returns an LMIInstanceName object.

In addition to listing all instance name objects or returning the first one, both instance_names() and first_instance_name() support an optional argument to allow you to filter the results:

```python
class_object.instance_names(criteria)

class_object.first_instance_name(criteria)
```

Replace `criteria` with a dictionary consisting of key-value pairs, where keys represent key properties and values represent required values of these key properties.

Example 20.27. Accessing Instance Names

To find the first instance name of the cls class object created in Example 20.7, “Accessing Class Objects” that has the Name key property equal to eth0 and assign it to a variable named `device_name`, type the following at the interactive prompt:

```python
> device_name = cls.first_instance_name({"Name": "eth0"})
>
```

Examining Instance Names

All instance name objects store information about their class name and the namespace they belong to.

To get the class name of a particular instance name object, use the following syntax:

```python
instance_name_object.classname
```
Replace *instance_name_object* with the name of the instance name object to inspect. This returns a string representation of the class name.

To get information about the namespace an instance name object belongs to, use:

```python
instance_name_object.namespace
```

This returns a string representation of the namespace.

**Example 20.28. Examining Instance Names**

To inspect the *device_name* instance name object created in Example 20.27, “Accessing Instance Names” and display its class name and the corresponding namespace, type the following at the interactive prompt:

```bash
> device_name.classname
u'LMI_IPNetworkConnection'
> device_name.namespace
'root/cimv2'
```

**Creating New Instance Names**

LMIShell allows you to create a new wrapped `CIMInstanceName` object if you know all primary keys of a remote object. This instance name object can then be used to retrieve the whole instance object.

To create a new instance name of a class object, use the `new_instance_name()` method as follows:

```python
class_object.new_instance_name(key_properties)
```

Replace *class_object* with the name of the class object and *key_properties* with a dictionary that consists of key-value pairs, where keys represent key properties and values represent key property values. This method returns an `LMIInstanceName` object.

**Example 20.29. Creating New Instance Names**

The `LMI_Account` class represents user accounts on the managed system. To use the `ns` namespace object created in Example 20.5, “Accessing Namespace Objects” and create a new instance name of the `LMI_Account` class representing the `lmishell-user` user on the managed system, type the following at the interactive prompt:

```bash
> instance_name = ns.LMI_Account.new_instance_name({
...     "CreationClassName" : "LMI_Account",
...     "Name" : "lmishell-user",
...     "SystemCreationClassName" : "PG_ComputerSystem",
...     "SystemName" : "server"})
```

**Listing and Accessing Key Properties**

To list all available key properties of a particular instance name object, use the `print_key_properties()` method as follows:
Replace `instance_name_object` with the name of the instance name object to inspect. This method prints available key properties to standard output.

To get a list of available key properties, use the `key_properties()` method:

```
instance_name_object.key_properties()
```

This method returns a list of strings.

**Example 20.30. Listing Available Key Properties**

To inspect the `device_name` instance name object created in Example 20.27, “Accessing Instance Names” and list all available key properties, type the following at the interactive prompt:

```
> device_name.print_key_properties()
CreationClassName
SystemName
Name
SystemCreationClassName
>
```

To assign a list of these key properties to a variable named `device_name_properties`, type:

```
> device_name_properties = device_name.key_properties()
```

To get the current value of a particular key property, use the following syntax:

```
instance_name_object.key_property_name
```

Replace `key_property_name` with the name of the key property to access.

**Example 20.31. Accessing Individual Key Properties**

To inspect the `device_name` instance name object created in Example 20.27, “Accessing Instance Names” and display the value of the key property named `SystemName`, type the following at the interactive prompt:

```
> device_name.SystemName
u'server.example.com'
```

**Converting Instance Names to Instances**

Each instance name can be converted to an instance. To do so, use the `to_instance()` method as follows:

```
instance_name_object.to_instance()
```
Replace `instance_name_object` with the name of the instance name object to convert. This method returns an `LMIInstance` object.

**Example 20.32. Converting Instance Names to Instances**

To convert the `device_name` instance name object created in Example 20.27, “Accessing Instance Names” to an instance object and assign it to a variable named `device`, type the following at the interactive prompt:

```
> device = device_name.to_instance()
```

20.4.7. Working with Associated Objects

The Common Information Model defines an association relationship between managed objects.

**Accessing Associated Instances**

To get a list of all objects associated with a particular instance object, use the `associators()` method as follows:

```
instance_object.associators(
    AssocClass=class_name,
    ResultClass=class_name,
    ResultRole=role,
    IncludeQualifiers=include_qualifiers,
    IncludeClassOrigin=include_class_origin,
    PropertyList=property_list)
```

To access the first object associated with a particular instance object, use the `first_associator()` method:

```
instance_object.first_associator(
    AssocClass=class_name,
    ResultClass=class_name,
    ResultRole=role,
    IncludeQualifiers=include_qualifiers,
    IncludeClassOrigin=include_class_origin,
    PropertyList=property_list)
```

Replace `instance_object` with the name of the instance object to inspect. You can filter the results by specifying the following parameters:

- **AssocClass** – Each returned object must be associated with the source object through an instance of this class or one of its subclasses. The default value is `None`.

- **ResultClass** – Each returned object must be either an instance of this class or one of its subclasses, or it must be this class or one of its subclasses. The default value is `None`.

- **Role** – Each returned object must be associated with the source object through an association in which the source object plays the specified role. The name of the property in the association class that refers to the source object must match the value of this parameter. The default value is `None`.
- **ResultRole** – Each returned object must be associated with the source object through an association in which the returned object plays the specified role. The name of the property in the association class that refers to the returned object must match the value of this parameter. The default value is None.

The remaining parameters refer to:

- **IncludeQualifiers** – A boolean indicating whether all qualifiers of each object (including qualifiers on the object and on any returned properties) should be included as QUALIFIER elements in the response. The default value is False.

- **IncludeClassOrigin** – A boolean indicating whether the CLASSORIGIN attribute should be present on all appropriate elements in each returned object. The default value is False.

- **PropertyList** – The members of this list define one or more property names. Returned objects will not include elements for any properties missing from this list. If **PropertyList** is an empty list, no properties are included in returned objects. If it is None, no additional filtering is defined. The default value is None.

**Example 20.33. Accessing Associated Instances**

The LMI_StorageExtent class represents block devices available in the system. To use the ns namespace object created in Example 20.5, “Accessing Namespace Objects”, create an instance of the LMI_StorageExtent class for the block device named /dev/vda, and assign it to a variable named vda, type the following at the interactive prompt:

```python
> vda = ns.LMI_StorageExtent.first_instance({
  ...
  "DeviceID" : "/dev/vda"
})
```

To get a list of all disk partitions on this block device and assign it to a variable named vda_partitions, use the `associators()` method as follows:

```python
> vda_partitions = vda.associators(ResultClass="LMI_DiskPartition")
```

**Accessing Associated Instance Names**

To get a list of all associated instance names of a particular instance object, use the `associator_names()` method as follows:

```python
instance_object.associator_names(
  AssocClass=class_name,
  ResultClass=class_name,
  Role=role,
  ResultRole=role)
```

To access the first associated instance name of a particular instance object, use the `first_associator_name()` method:

```python
instance_object.first_associator_name(
  AssocClass=class_object,
  ResultClass=class_object,
```
Role=role,
ResultRole=role)

Replace \textit{instance\_object} with the name of the instance object to inspect. You can filter the results by specifying the following parameters:

- \textbf{AssocClass} — Each returned name identifies an object that must be associated with the source object through an instance of this class or one of its subclasses. The default value is \texttt{None}.

- \textbf{ResultClass} — Each returned name identifies an object that must be either an instance of this class or one of its subclasses, or it must be this class or one of its subclasses. The default value is \texttt{None}.

- \textbf{Role} — Each returned name identifies an object that must be associated with the source object through an association in which the source object plays the specified role. The name of the property in the association class that refers to the source object must match the value of this parameter. The default value is \texttt{None}.

- \textbf{ResultRole} — Each returned name identifies an object that must be associated with the source object through an association in which the returned named object plays the specified role. The name of the property in the association class that refers to the returned object must match the value of this parameter. The default value is \texttt{None}.

\textbf{Example 20.34. Accessing Associated Instance Names}

To use the \texttt{vda} instance object created in Example 20.33, \textit{“Accessing Associated Instances”}, get a list of its associated instance names, and assign it to a variable named \texttt{vda\_partitions}, type:

\begin{verbatim}
> vda_partitions = vda.associator_names(ResultClass="LMI_DiskPartition")
\end{verbatim}

\textbf{20.4.8. Working with Association Objects}

The Common Information Model defines an association relationship between managed objects. Association objects define the relationship between two other objects.

\textbf{Accessing Association Instances}

To get a list of association objects that refer to a particular target object, use the \texttt{references()} method as follows:

\begin{verbatim}
instance\_object.references(
    ResultClass=class\_name,
    Role=role,
    IncludeQualifiers=include\_qualifiers,
    IncludeClassOrigin=include\_class\_origin,
    PropertyList=property\_list)
\end{verbatim}

To access the first association object that refers to a particular target object, use the \texttt{first\_reference()} method:

\begin{verbatim}
instance\_object.first\_reference(
    ...  ResultClass=class\_name,
\end{verbatim}
Replace *instance_object* with the name of the instance object to inspect. You can filter the results by specifying the following parameters:

- **ResultClass** – Each returned object must be either an instance of this class or one of its subclasses, or it must be this class or one of its subclasses. The default value is None.

- **Role** – Each returned object must refer to the target object through a property with a name that matches the value of this parameter. The default value is None.

The remaining parameters refer to:

- **IncludeQualifiers** – A boolean indicating whether each object (including qualifiers on the object and on any returned properties) should be included as a QUALIFIER element in the response. The default value is False.

- **IncludeClassOrigin** – A boolean indicating whether the CLASSORIGIN attribute should be present on all appropriate elements in each returned object. The default value is False.

- **PropertyList** – The members of this list define one or more property names. Returned objects will not include elements for any properties missing from this list. If *PropertyList* is an empty list, no properties are included in returned objects. If it is None, no additional filtering is defined. The default value is None.

### Example 20.35. Accessing Association Instances

The *LMI_LANEndpoint* class represents a communication endpoint associated with a certain network interface device. To use the *ns* namespace object created in Example 20.5, “Accessing Namespace Objects”, create an instance of the *LMI_LANEndpoint* class for the network interface device named *eth0*, and assign it to a variable named *lan_endpoint*, type the following at the interactive prompt:

```python
> lan_endpoint = ns.LMI_LANEndpoint.first_instance({
    "Name" : "eth0"})
```

To access the first association object that refers to an *LMI_BindsToLANEndpoint* object and assign it to a variable named *bind*, type:

```python
> bind = lan_endpoint.first_reference(ResultClass="LMI_BindsToLANEndpoint")
```

You can now use the *Dependent* property to access the dependent *LMI_IPProtocolEndpoint* class that represents the IP address of the corresponding network interface device:

```python
> ip = bind.Dependent.to_instance()  
> print ip.IPv4Address
192.168.122.1
```
Accessing Association Instance Names
To get a list of association instance names of a particular instance object, use the reference_names() method as follows:

```python
instance_object.reference_names(
    ResultClass=class_name,
    Role=role)
```

To access the first association instance name of a particular instance object, use the first_reference_name() method:

```python
instance_object.first_reference_name(
    ResultClass=class_name,
    Role=role)
```

Replace `instance_object` with the name of the instance object to inspect. You can filter the results by specifying the following parameters:

- **ResultClass** – Each returned object name identifies either an instance of this class or one of its subclasses, or this class or one of its subclasses. The default value is `None`.

- **Role** – Each returned object identifies an object that refers to the target instance through a property with a name that matches the value of this parameter. The default value is `None`.

Example 20.36. Accessing Association Instance Names
To use the `lan_endpoint` instance object created in Example 20.35, “Accessing Association Instances”, access the first association instance name that refers to an `LMI_BindsToLANEndpoint` object, and assign it to a variable named `bind`, type:

```python
bind = lan_endpoint.first_reference_name(...
    ResultClass="LMI_BindsToLANEndpoint")
```

You can now use the `Dependent` property to access the dependent `LMI_IPProtocolEndpoint` class that represents the IP address of the corresponding network interface device:

```python
ip = bind.Dependent.to_instance()
print ip.IPv4Address
192.168.122.1
```

20.4.9. Working with Indications
Indication is a reaction to a specific event that occurs in response to a particular change in data. LMIShell can subscribe to an indication in order to receive such event responses.

Subscribing to Indications
To subscribe to an indication, use the subscribe_indication() method as follows:
connection_object.subscribe_indication(
    QueryLanguage="WQL",
    Query='SELECT * FROM CIM_InstModification',
    Name="cpu",
    CreationNamespace="root/interop",
    SubscriptionCreationClassName="CIM_IndicationSubscription",
    FilterCreationClassName="CIM_IndicationFilter",
    FilterSystemCreationClassName="CIM_ComputerSystem",
    FilterSourceNamespace="root/cimv2",
    HandlerCreationClassName="CIM_IndicationHandlerCIMXML",
    HandlerSystemCreationClassName="CIM_ComputerSystem",
    Destination="http://host_name:5988")

Alternatively, you can use a shorter version of the method call as follows:

c.subscribe_indication(
    Query='SELECT * FROM CIM_InstModification',
    Name="cpu",
    Destination="http://host_name:5988")

Replace connection_object with a connection object and host_name with the host name of the system you want to deliver the indications to.

By default, all subscriptions created by the LMIShell interpreter are automatically deleted when the interpreter terminates. To change this behavior, pass the Permanent=True keyword parameter to the subscribe_indication() method call. This will prevent LMIShell from deleting the subscription.

Example 20.37. Subscribing to Indications

To use the c connection object created in Example 20.1, “Connecting to a Remote CIMOM” and subscribe to an indication named cpu, type the following at the interactive prompt:

> c.subscribe_indication(
    ... QueryLanguage="WQL",
    ... Query='SELECT * FROM CIM_InstModification',
    ... Name="cpu",
    ... CreationNamespace="root/interop",
    ... SubscriptionCreationClassName="CIM_IndicationSubscription",
    ... FilterCreationClassName="CIM_IndicationFilter",
    ... FilterSystemCreationClassName="CIM_ComputerSystem",
    ... FilterSourceNamespace="root/cimv2",
    ... HandlerCreationClassName="CIM_IndicationHandlerCIMXML",
    ... HandlerSystemCreationClassName="CIM_ComputerSystem",
    ... Destination="http://server.example.com:5988")
LMIReturnValue(rval=True, rparams=NocaseDict({}), errorstr='')

Listing Subscribed Indications

To list all the subscribed indications, use the print_subscribed_indications() method as follows:

connection_object.print_subscribed_indications()
Replace \textit{connection\_object} with the name of the connection object to inspect. This method prints subscribed indications to standard output.

To get a list of subscribed indications, use the \texttt{subscribed\_indications()} method:

\begin{verbatim}
connection\_object.subscribed\_indications()
\end{verbatim}

This method returns a list of strings.

\textbf{Example 20.38. Listing Subscribed Indications}

To inspect the \texttt{c} connection object created in Example 20.1, “Connecting to a Remote CIMOM” and list all subscribed indications, type the following at the interactive prompt:

\begin{verbatim}
> c.print_subscribed_indications()
> \\
To assign a list of these indications to a variable named \texttt{indications}, type:

\begin{verbatim}
> indications = c.subscribed_indications()
> \\
\end{verbatim}

\textbf{Unsubscribing from Indications}

By default, all subscriptions created by the LMIShell interpreter are automatically deleted when the interpreter terminates. To delete an individual subscription sooner, use the \texttt{unsubscribe\_indication()} method as follows:

\begin{verbatim}
connection\_object.unsubscribe\_indication(indication\_name)
\end{verbatim}

Replace \texttt{connection\_object} with the name of the connection object and \texttt{indication\_name} with the name of the indication to delete.

To delete all subscriptions, use the \texttt{unsubscribe\_all\_indications()} method:

\begin{verbatim}
connection\_object.unsubscribe\_all\_indications()
\end{verbatim}

\textbf{Example 20.39. Unsubscribing from Indications}

To use the \texttt{c} connection object created in Example 20.1, “Connecting to a Remote CIMOM” and unsubscribe from the indication created in Example 20.37, “Subscribing to Indications”, type the following at the interactive prompt:

\begin{verbatim}
> c.unsubscribe\_indication('cpu')
LMIReturnValue(rval=True, rparams=NcaseDict({}), errorstr='')
> \\
\end{verbatim}

\textbf{Implementing an Indication Handler}

The \texttt{subscribe\_indication()} method allows you to specify the host name of the system you want to deliver the indications to. The following example shows how to implement an indication handler:
The first argument of the handler is an LmiIndication object, which contains a list of methods and objects exported by the indication. Other parameters are user specific: those arguments need to be specified when adding a handler to the listener.

In the example above, the add_handler() method call uses a special string with eight “X” characters. These characters are replaced with a random string that is generated by listeners in order to avoid a possible handler name collision. To use the random string, start the indication listener first and then subscribe to an indication so that the Destination property of the handler object contains the following value: schema://host_name/random_string.

Example 20.40. Implementing an Indication Handler

The following script illustrates how to write a handler that monitors a managed system located at 192.168.122.1 and calls the indication_callback() function whenever a new user account is created:

```python
#!/usr/bin/lmishell

import sys
from time import sleep
from lmi.shell.LMIUtil import LMIPassByRef
from lmi.shell.LMIIndicationListener import LMIIndicationListener

# These are passed by reference to indication_callback
var1 = LMIPassByRef("some_value")
var2 = LMIPassByRef("some_other_value")

def indication_callback(ind, var1, var2):
    # Do something with ind, var1 and var2
    print ind.exported_objects()
    print var1.value
    print var2.value

c = connect("hostname", "username", "password")

listener = LMIIndicationListener("0.0.0.0", 65500)
unique_name = listener.add_handler("demo-XXXXXXXX", indication_callback, var1, var2)

listener.start()

print c.subscribe_indication(  # Example of subscribing to an indication
...  )
```
20.4.10. Example Usage

This section provides a number of examples for various CIM providers distributed with the OpenLMI packages. All examples in this section use the following two variable definitions:

```
c = connect("host_name", "user_name", "password")
ns = c.root.cimv2
```

Replace `host_name` with the host name of the managed system, `user_name` with the name of user that is allowed to connect to OpenPegasus CIMOM running on that system, and `password` with the user's password.

Using the OpenLMI Service Provider

The `openlmi-service` package installs a CIM provider for managing system services. The examples below illustrate how to use this CIM provider to list available system services and how to start, stop, enable, and disable them.

Example 20.41. Listing Available Services

To list all available services on the managed machine along with information regarding whether the service has been started (TRUE) or stopped (FALSE) and the status string, use the following code snippet:

```
for service in ns.LMI_Service.instances():
    print "%s:\t%s" % (service.Name, service.Status)
```

To list only the services that are enabled by default, use this code snippet:

```
cups = ns.LMI_Service.first_instance({"Name": "cups.service"})
cups.doc()
```
Example 20.42. Starting and Stopping Services
To start and stop the cups service and to see its current status, use the following code snippet:

```python
cups = ns.LMI_Service.first_instance({"Name": "cups.service"})
cups.StartService()
print cups.Status
cups.StopService()
print cups.Status
```

Example 20.43. Enabling and Disabling Services
To enable and disable the cups service and to display its EnabledDefault property, use the following code snippet:

```python
cups = ns.LMI_Service.first_instance({"Name": "cups.service"})
cups.TurnServiceOff()
print cups.EnabledDefault
cups.TurnServiceOn()
print cups.EnabledDefault
```

Using the OpenLMI Networking Provider
The openlmi-networking package installs a CIM provider for networking. The examples below illustrate how to use this CIM provider to list IP addresses associated with a certain port number, create a new connection, configure a static IP address, and activate a connection.

Example 20.44. Listing IP Addresses Associated with a Given Port Number
To list all IP addresses associated with the eth0 network interface, use the following code snippet:

```python
device = ns.LMI_IPNetworkConnection.first_instance({'ElementName': 'eth0'})
for endpoint in device.associators(AssocClass="LMI_NetworkSAPSAPDependency", ResultClass="LMI_IPProtocolEndpoint"):
    if endpoint.ProtocolIFType == ns.LMI_IPProtocolEndpoint.ProtocolIFTypeValues.IPv4:
        print "IPv4: %s/%s" % (endpoint.IPv4Address, endpoint.SubnetMask)
    elif endpoint.ProtocolIFType == ns.LMI_IPProtocolEndpoint.ProtocolIFTypeValues.IPv6:
        print "IPv6: %s/%d" % (endpoint.IPv6Address, endpoint.IPv6SubnetPrefixLength)
```

This code snippet uses the LMI_IPProtocolEndpoint class associated with a given LMI_IPNetworkConnection class.

To display the default gateway, use this code snippet:

```python
for rsap in
The default gateway is represented by an `LMI_NetworkRemoteServiceAccessPoint` instance with the `AccessContext` property equal to `DefaultGateway`.

To get a list of DNS servers, the object model needs to be traversed as follows:

1. Get the `LMI_IPProtocolEndpoint` instances associated with a given `LMI_IPNetworkConnection` using `LMI_NetworkSAPSAPDependency`.

2. Use the same association for the `LMI_DNSProtocolEndpoint` instances.

The `LMI_NetworkRemoteServiceAccessPoint` instances with the `AccessContext` property equal to the DNS Server associated through `LMI_NetworkRemoteAccessAvailableToElement` have the DNS server address in the `AccessInfo` property.

There can be more possible paths to get to the `RemoteServiceAccessPath` and entries can be duplicated. The following code snippet uses the `set()` function to remove duplicate entries from the list of DNS servers:

```python
dnsservers = set()
for ipendpoint in device.associators(AssocClass="LMI_NetworkSAPSAPDependency", ResultClass="LMI_IPProtocolEndpoint"):
    for dnsedpoint in ipendpoint.associators(AssocClass="LMI_NetworkSAPSAPDependency", ResultClass="LMI_DNSProtocolEndpoint"):
        for rsap in dnsedpoint.associators(AssocClass="LMI_NetworkRemoteAccessAvailableToElement", ResultClass="LMI_NetworkRemoteServiceAccessPoint"):
                dnsservers.add(rsap.AccessInfo)
print "DNS: ", ", ".join(dnsservers)
```

Example 20.45. Creating a New Connection and Configuring a Static IP Address

To create a new setting with a static IPv4 and stateless IPv6 configuration for network interface `eth0`, use the following code snippet:

```python
capability = ns.LMI_IPNetworkConnectionCapabilities.first_instance({
    'ElementName': 'eth0' })
result = capability.LMI_CreateIPSetting(Caption='eth0 Static',
IPv4Type=capability.LMI_CreateIPSetting.IPv4TypeValues.Static,
IPv6Type=capability.LMI_CreateIPSetting.IPv6TypeValues.Stateless)
setting = result.rparams["SettingData"].to_instance()
for settingData in setting.associators(AssocClass="LMI_OrderedIPAssignmentComponent"):
```

430
This code snippet creates a new setting by calling the `LMI_CreateIPSetting()` method on the instance of `LMI_IPNetworkConnectionCapabilities`, which is associated with `LMI_IPNetworkConnection` through `LMI_IPNetworkConnectionElementCapabilities`. It also uses the `push()` method to modify the setting.

Example 20.46. Activating a Connection

To apply a setting to the network interface, call the `ApplySettingToIPNetworkConnection()` method of the `LMI_IPConfigurationService` class. This method is asynchronous and returns a job. The following code snippets illustrates how to call this method synchronously:

```python
if setting.ProtocolIFType ==
ns.LMI_IPAssignmentSettingData.ProtocolIFTypeValues.IPv4:
    # Set static IPv4 address
    settingData.IPAddresses = ["192.168.1.100"]
    settingData.SubnetMasks = ["255.255.0.0"]
    settingData.GatewayAddresses = ["192.168.1.1"]
    settingData.push()

setting = ns.LMI_IPAssignmentSettingData.first_instance({ "Caption": "eth0 Static" })
port = ns.LMI_IPNetworkConnection.first_instance({ 'ElementName': 'ens8' })
service = ns.LMI_IPConfigurationService.first_instance()
service.SyncApplySettingToIPNetworkConnection(SettingData=setting,
                                                IPNetworkConnection=port,
                                                Mode=32768)
```

The **Mode** parameter affects how the setting is applied. The most commonly used values of this parameter are as follows:

- **1** — apply the setting now and make it auto-activated.
- **2** — make the setting auto-activated and do not apply it now.
- **4** — disconnect and disable auto-activation.
- **5** — do not change the setting state, only disable auto-activation.
- **32768** — apply the setting.
- **32769** — disconnect.

Using the OpenLMI Storage Provider

The openlmi-storage package installs a CIM provider for storage management. The examples below illustrate how to use this CIM provider to create a volume group, create a logical volume, build a file system, mount a file system, and list block devices known to the system.

In addition to the `c` and `ns` variables, these examples use the following variable definitions:

```python
MEGABYTE = 1024*1024
storage_service = ns.LMI_StorageConfigurationService.first_instance()
filesystem_service =
```
Example 20.47. Creating a Volume Group

To create a new volume group located in /dev/myGroup/ that has three members and the default extent size of 4 MB, use the following code snippet:

```python
ns.LMI_FileSystemConfigurationService.first_instance()

# Find the devices to add to the volume group
# (filtering the CIM_StorageExtent.instances() call would be faster, but this is easier to read):
sda1 = ns.CIM_StorageExtent.first_instance({"Name": "/dev/sda1"})
sdb1 = ns.CIM_StorageExtent.first_instance({"Name": "/dev/sdb1"})
sdc1 = ns.CIM_StorageExtent.first_instance({"Name": "/dev/sdc1"})

# Create a new volume group:
(ret, outparams, err) = storage_service.SyncCreateOrModifyVG(
    ElementName="myGroup",
    InExtents=[sda1, sdb1, sdc1])
vg = outparams['Pool'].to_instance()

# Find the volume group:
vg = ns.LMI_VGStoragePool.first_instance({"Name": "/dev/mapper/myGroup"})

# Create the first logical volume:
(ret, outparams, err) = storage_service.SyncCreateOrModifyLV(
    ElementName="Vol1",
    InPool=vg,
    Size=100 * MEGABYTE)
lv = outparams['TheElement'].to_instance()

# Create the second logical volume:
(ret, outparams, err) = storage_service.SyncCreateOrModifyLV(
    ElementName="Vol2",
    InPool=vg,
    Size=100 * MEGABYTE)
lv = outparams['TheElement'].to_instance()
```

Example 20.48. Creating a Logical Volume

To create two logical volumes with the size of 100 MB, use this code snippet:

Example 20.49. Creating a File System
To create an ext3 file system on logical volume lv from Example 20.48, “Creating a Logical Volume”, use the following code snippet:

```
(ret, outparams, err) = filesystem_service.SyncLMI_CreateFileSystem(
    FileSystemType=filesystem_service.LMI_CreateFileSystem.FileSystemTypeValues.EXT3,
    InExtents=[lv])
```

**Example 20.50. Mounting a File System**

To mount the file system created in Example 20.49, “Creating a File System”, use the following code snippet:

```
# Find the file system on the logical volume:
fs = lv.first_associator(ResultClass="LMI_LocalFileSystem")

mount_service = ns.LMI_MountConfigurationService.first_instance()
(rc, out, err) = mount_service.SyncCreateMount(
    FileSystemType='ext3',
    Mode=32768, # just mount
    FileSystem=fs,
    MountPoint='/mnt/test',
    FileSystemSpec=lv.Name)
```

**Example 20.51. Listing Block Devices**

To list all block devices known to the system, use the following code snippet:

```
devices = ns.CIM_StorageExtent.instances()
for device in devices:
    if lmi_isinstance(device, ns.CIM_Memory):
        # Memory and CPU caches are StorageExtents too, do not print them
        continue
    print device.classname,
    print device.DeviceID,
    print device.Name,
    print device.BlockSize*device.NumberOfBlocks
```

**Using the OpenLMI Hardware Provider**

The openlmi-hardware package installs a CIM provider for monitoring hardware. The examples below illustrate how to use this CIM provider to retrieve information about CPU, memory modules, PCI devices, and the manufacturer and model of the machine.

**Example 20.52. Viewing CPU Information**

To display basic CPU information such as the CPU name, the number of processor cores, and the number of hardware threads, use the following code snippet:
Example 20.53. Viewing Memory Information

To display basic information about memory modules such as their individual sizes, use the following code snippet:

```python
mem = ns.LMI_Memory.first_instance()
for i in mem.associators(ResultClass="LMI_PhysicalMemory"):
    print i.Name
```

Example 20.54. Viewing Chassis Information

To display basic information about the machine such as its manufacturer or its model, use the following code snippet:

```python
chassis = ns.LMI_Chassis.first_instance()
print chassis.Manufacturer
print chassis.Model
```

Example 20.55. Listing PCI Devices

To list all PCI devices known to the system, use the following code snippet:

```python
for pci in ns.LMI_PCIDevice.instances():
    print pci.Name
```

20.5. USING OPENLMI SCRIPTS

The LMIShell interpreter is built on top of Python modules that can be used to develop custom management tools. The OpenLMI Scripts project provides a number of Python libraries for interfacing with OpenLMI providers. In addition, it is distributed with lmi, an extensible utility that can be used to interact with these libraries from the command line.

To install OpenLMI Scripts on your system, type the following at a shell prompt:

```
easy_install --user openlmi-scripts
```

This command installs the Python modules and the lmi utility in the ~/.local/ directory. To extend the functionality of the lmi utility, install additional OpenLMI modules by using the following command:

```
easy_install --user package_name
```
For a complete list of available modules, see the Python website. For more information about OpenLMI Scripts, see the official OpenLMI Scripts documentation.

20.6. ADDITIONAL RESOURCES

For more information about OpenLMI and system management in general, see the resources listed below.

Installed Documentation

- `lmishell(1)` – The manual page for the `lmishell` client and interpreter provides detailed information about its execution and usage.

Online Documentation

- **Red Hat Enterprise Linux 7 Networking Guide** – The *Networking Guide* for Red Hat Enterprise Linux 7 documents relevant information regarding the configuration and administration of network interfaces and network services on the system.

- **Red Hat Enterprise Linux 7 Power Management Guide** – The *Power Management Guide* for Red Hat Enterprise Linux 7 explains how to manage power consumption of the system effectively. It discusses different techniques that lower power consumption for both servers and laptops, and explains how each technique affects the overall performance of the system.

- **FreeIPA Documentation** – The *FreeIPA Documentation* serves as the primary user documentation for using the FreeIPA Identity Management project.

- **OpenSSL Home Page** – The OpenSSL home page provides an overview of the OpenSSL project.

- **Mozilla NSS Documentation** – The *Mozilla NSS Documentation* serves as the primary user documentation for using the Mozilla NSS project.

See Also

- **Chapter 3, Managing Users and Groups** documents how to manage system users and groups in the graphical user interface and on the command line.

- **Chapter 8, Yum** describes how to use the Yum package manager to search, install, update, and uninstall packages on the command line.

- **Chapter 9, Managing Services with systemd** provides an introduction to systemd and documents how to use the `systemctl` command to manage system services, configure systemd targets, and execute power management commands.

- **Chapter 11, OpenSSH** describes how to configure an SSH server and how to use the `ssh`, `scp`, and `sftp` client utilities to access it.
CHAPTER 21. VIEWING AND MANAGING LOG FILES

Log files are files that contain messages about the system, including the kernel, services, and applications running on it. There are different log files for different information. For example, there is a default system log file, a log file just for security messages, and a log file for cron tasks.

Log files can be very useful when trying to troubleshoot a problem with the system such as trying to load a kernel driver or when looking for unauthorized login attempts to the system. This chapter discusses where to find log files, how to view log files, and what to look for in log files.

Some log files are controlled by a daemon called rsyslogd. The rsyslogd daemon is an enhanced replacement for sysklogd, and provides extended filtering, encryption protected relaying of messages, various configuration options, input and output modules, support for transportation via the TCP or UDP protocols. Note that rsyslog is compatible with sysklogd.

Log files can also be managed by the journald daemon – a component of systemd. The journald daemon captures Syslog messages, kernel log messages, initial RAM disk and early boot messages as well as messages written to standard output and standard error output of all services, indexes them and makes this available to the user. The native journal file format, which is a structured and indexed binary file, improves searching and provides faster operation, and it also stores meta data information like time stamps or user IDs. Log files produced by journald are by default not persistent, log files are stored only in memory or a small ring-buffer in the /run/log/journal/ directory. The amount of logged data depends on free memory, when you reach the capacity limit, the oldest entries are deleted. However, this setting can be altered – see Section 21.10.5, “Enabling Persistent Storage”. For more information on Journal see Section 21.10, “Using the Journal”.

By default, these two logging tools coexist on your system. The journald daemon is the primary tool for troubleshooting. It also provides additional data necessary for creating structured log messages. Data acquired by journald is forwarded into the /run/systemd/journal/syslog socket that may be used by rsyslogd to process the data further. However, rsyslog does the actual integration by default via the imjournal input module, thus avoiding the aforementioned socket. You can also transfer data in the opposite direction, from rsyslogd to journald with use of omjournal module. See Section 21.7, “Interaction of Rsyslog and Journal” for further information. The integration enables maintaining text-based logs in a consistent format to ensure compatibility with possible applications or configurations dependent on rsyslogd. Also, you can maintain rsyslog messages in a structured format (see Section 21.8, “Structured Logging with Rsyslog”).

21.1. LOCATING LOG FILES

A list of log files maintained by rsyslogd can be found in the /etc/rsyslog.conf configuration file. Most log files are located in the /var/log/ directory. Some applications such as httpd and samba have a directory within /var/log/ for their log files.

You may notice multiple files in the /var/log/ directory with numbers after them (for example, cron-20100906). These numbers represent a time stamp that has been added to a rotated log file. Log files are rotated so their file sizes do not become too large. The logrotate package contains a cron task that automatically rotates log files according to the /etc/logrotate.conf configuration file and the configuration files in the /etc/logrotate.d/ directory.

21.2. BASIC CONFIGURATION OF RSYSLOG

The main configuration file for rsyslog is /etc/rsyslog.conf. Here, you can specify global directives, modules, and rules that consist of filter and action parts. Also, you can add comments in the form of text following a hash sign (#).
21.2.1. Filters

A rule is specified by a filter part, which selects a subset of syslog messages, and an action part, which specifies what to do with the selected messages. To define a rule in your /etc/rsyslog.conf configuration file, define both, a filter and an action, on one line and separate them with one or more spaces or tabs.

rsyslog offers various ways to filter syslog messages according to selected properties. The available filtering methods can be divided into Facility/Priority-based, Property-based, and Expression-based filters.

**Facility/Priority-based filters**

The most used and well-known way to filter syslog messages is to use the facility/priority-based filters which filter syslog messages based on two conditions: facility and priority separated by a dot.

To create a selector, use the following syntax:

```
FACILITY.PRIORITY
```

where:

- **FACILITY** specifies the subsystem that produces a specific syslog message. For example, the mail subsystem handles all mail-related syslog messages. FACILITY can be represented by one of the following keywords (or by a numerical code): kern (0), user (1), mail (2), daemon (3), auth (4), syslog (5), lpr (6), news (7), uucp (8), cron (9), authpriv (10), ftp (11), and local0 through local7 (16 - 23).

- **PRIORITY** specifies a priority of a syslog message. PRIORITY can be represented by one of the following keywords (or by a number): debug (7), info (6), notice (5), warning (4), err (3), crit (2), alert (1), and emerg (0).

The aforementioned syntax selects syslog messages with the defined or higher priority. By preceding any priority keyword with an equal sign (=), you specify that only syslog messages with the specified priority will be selected. All other priorities will be ignored. Conversely, preceding a priority keyword with an exclamation mark (!) selects all syslog messages except those with the defined priority.

In addition to the keywords specified above, you may also use an asterisk (*) to define all facilities or priorities (depending on where you place the asterisk, before or after the comma). Specifying the priority keyword none serves for facilities with no given priorities. Both facility and priority conditions are case-insensitive.

To define multiple facilities and priorities, separate them with a comma (,). To define multiple selectors on one line, separate them with a semi-colon (;). Note that each selector in the selector field is capable of overwriting the preceding ones, which can exclude some priorities from the pattern.

**Example 21.1. Facility/Priority-based Filters**

The following are a few examples of simple facility/priority-based filters that can be specified in /etc/rsyslog.conf. To select all kernel syslog messages with any priority, add the following text into the configuration file:

```
kern.*
```

To select all mail syslog messages with priority crit and higher, use this form:
To select all cron syslog messages except those with the `info` or `debug` priority, set the configuration in the following form:

```
cron.!info,!debug
```

**Property-based filters**

Property-based filters let you filter syslog messages by any property, such as `timegenerated` or `syslogtag`. For more information on properties, see the section called “Properties”. You can compare each of the specified properties to a particular value using one of the compare-operations listed in Table 21.1, “Property-based compare-operations”. Both property names and compare operations are case-sensitive.

Property-based filter must start with a colon (:``). To define the filter, use the following syntax:

```
:PROPERTY, [!]COMPARE_OPERATION, "STRING"
```

where:

- The `PROPERTY` attribute specifies the desired property.
- The optional exclamation point (`!`) negates the output of the compare-operation. Other Boolean operators are currently not supported in property-based filters.
- The `COMPARE_OPERATION` attribute specifies one of the compare-operations listed in Table 21.1, “Property-based compare-operations”.
- The `STRING` attribute specifies the value that the text provided by the property is compared to. This value must be enclosed in quotation marks. To escape certain character inside the string (for example a quotation mark (`"`)), use the backslash character (`\`).

**Table 21.1. Property-based compare-operations**

<table>
<thead>
<tr>
<th>Compare-operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contains</code></td>
<td>Checks whether the provided string matches any part of the text provided by the property. To perform case-insensitive comparisons, use <code>contains_i</code>.</td>
</tr>
<tr>
<td><code>isequal</code></td>
<td>Compares the provided string against all of the text provided by the property. These two values must be exactly equal to match.</td>
</tr>
<tr>
<td><code>startswith</code></td>
<td>Checks whether the provided string is found exactly at the beginning of the text provided by the property. To perform case-insensitive comparisons, use <code>startswith_i</code>.</td>
</tr>
<tr>
<td><code>regex</code></td>
<td>Compares the provided POSIX BRE (Basic Regular Expression) against the text provided by the property.</td>
</tr>
<tr>
<td>Compare-operation</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><em>ereregex</em></td>
<td>Compares the provided POSIX ERE (Extended Regular Expression) regular expression against the text provided by the property.</td>
</tr>
<tr>
<td><em>isempty</em></td>
<td>Checks if the property is empty. The value is discarded. This is especially useful when working with normalized data, where some fields may be populated based on normalization result.</td>
</tr>
</tbody>
</table>

**Example 21.2. Property-based Filters**

The following are a few examples of property-based filters that can be specified in `/etc/rsyslog.conf`. To select syslog messages which contain the string `error` in their message text, use:

```
:msg, contains, "error"
```

The following filter selects syslog messages received from the host name `host1`:

```
:hostname, isequal, "host1"
```

To select syslog messages which do not contain any mention of the words `fatal` and `error` with any or no text between them (for example, `fatal lib error`), type:

```
:msg, !regex, "fatal .* error"
```

**Expression-based filters**

Expression-based filters select syslog messages according to defined arithmetic, Boolean or string operations. Expression-based filters use `rsyslog`’s own scripting language called `RainerScript` to build complex filters.

The basic syntax of expression-based filter looks as follows:

```
if EXPRESSION then ACTION else ACTION
```

where:

- The `EXPRESSION` attribute represents an expression to be evaluated, for example: `$msg startswith 'DEVNAME'` or `$syslogfacility-text == 'local0'`. You can specify more than one expression in a single filter by using `and` and `or` operators.

- The `ACTION` attribute represents an action to be performed if the expression returns the value `true`. This can be a single action, or an arbitrary complex script enclosed in curly braces.

- Expression-based filters are indicated by the keyword `if` at the start of a new line. The `then` keyword separates the `EXPRESSION` from the `ACTION`. Optionally, you can employ the `else` keyword to specify what action is to be performed in case the condition is not met.
With expression-based filters, you can nest the conditions by using a script enclosed in curly braces as in Example 21.3, “Expression-based Filters”. The script allows you to use facility/priority-based filters inside the expression. On the other hand, property-based filters are not recommended here. RainerScript supports regular expressions with specialized functions `re_match()` and `re_extract()`.

Example 21.3. Expression-based Filters

The following expression contains two nested conditions. The log files created by a program called `prog1` are split into two files based on the presence of the "test" string in the message.

```plaintext
if $programname == 'prog1' then {
    action(type="omfile" file="/var/log/prog1.log")
    if $msg contains 'test' then
        action(type="omfile" file="/var/log/prog1test.log")
    else
        action(type="omfile" file="/var/log/prog1notest.log")
}
```

See the section called “Online Documentation” for more examples of various expression-based filters. RainerScript is the basis for `rsyslog`'s new configuration format, see Section 21.3, “Using the New Configuration Format”

21.2.2. Actions

Actions specify what is to be done with the messages filtered out by an already defined selector. The following are some of the actions you can define in your rule:

**Saving syslog messages to log files**

The majority of actions specify to which log file a syslog message is saved. This is done by specifying a file path after your already-defined selector:

```
FILTER  PATH
```

where FILTER stands for user-specified selector and PATH is a path of a target file.

For instance, the following rule is comprised of a selector that selects all cron syslog messages and an action that saves them into the `/var/log/cron.log` log file:

```
cron.* /var/log/cron.log
```

By default, the log file is synchronized every time a syslog message is generated. Use a dash mark (-) as a prefix of the file path you specified to omit syncing:

```
FILTER  -PATH
```

Note that you might lose information if the system terminates right after a write attempt. However, this setting can improve performance, especially if you run programs that produce very verbose log messages.
Your specified file path can be either static or dynamic. Static files are represented by a fixed file path as shown in the example above. Dynamic file paths can differ according to the received message. Dynamic file paths are represented by a template and a question mark (?) prefix:

```
FILTER ?DynamicFile
```

where DynamicFile is a name of a predefined template that modifies output paths. You can use the dash prefix (-) to disable syncing, also you can use multiple templates separated by a colon (:). For more information on templates, see the section called “Generating Dynamic File Names”.

If the file you specified is an existing terminal or /dev/console device, syslog messages are sent to standard output (using special terminal-handling) or your console (using special /dev/console-handling) when using the X Window System, respectively.

Sending syslog messages over the network
rsyslog allows you to send and receive syslog messages over the network. This feature allows you to administer syslog messages of multiple hosts on one machine. To forward syslog messages to a remote machine, use the following syntax:

```
@[(zNUMBER)]HOST:[PORT]
```

where:
- The at sign (@) indicates that the syslog messages are forwarded to a host using the UDP protocol. To use the TCP protocol, use two at signs with no space between them ( @@).
- The optional zNUMBER setting enables zlib compression for syslog messages. The NUMBER attribute specifies the level of compression (from 1 – lowest to 9 – maximum). Compression gain is automatically checked by rsyslogd, messages are compressed only if there is any compression gain and messages below 60 bytes are never compressed.
- The HOST attribute specifies the host which receives the selected syslog messages.
- The PORT attribute specifies the host machine's port.

When specifying an IPv6 address as the host, enclose the address in square brackets ([ , ]).

Example 21.4. Sending syslog Messages over the Network
The following are some examples of actions that forward syslog messages over the network (note that all actions are preceded with a selector that selects all messages with any priority). To forward messages to 192.168.0.1 via the UDP protocol, type:

```
*.* @192.168.0.1
```

To forward messages to "example.com" using port 6514 and the TCP protocol, use:

```
*.* @@example.com:6514
```

The following compresses messages with zlib (level 9 compression) and forwards them to 2001:db8::1 using the UDP protocol

```
*.* @(z9)[2001:db8::1]
```
Output channels

Output channels are primarily used to specify the maximum size a log file can grow to. This is very useful for log file rotation (for more information see Section 21.2.5, “Log Rotation”). An output channel is basically a collection of information about the output action. Output channels are defined by the $outchannel directive. To define an output channel in /etc/rsyslog.conf, use the following syntax:

```
$outchannel NAME, FILE_NAME, MAX_SIZE, ACTION
```

where:

- The `NAME` attribute specifies the name of the output channel.
- The `FILE_NAME` attribute specifies the name of the output file. Output channels can write only into files, not pipes, terminal, or other kind of output.
- The `MAX_SIZE` attribute represents the maximum size the specified file (in `FILE_NAME`) can grow to. This value is specified in bytes.
- The `ACTION` attribute specifies the action that is taken when the maximum size, defined in `MAX_SIZE`, is hit.

To use the defined output channel as an action inside a rule, type:

```
FILTER :omfile:$NAME
```

**Example 21.5. Output channel log rotation**

The following output shows a simple log rotation through the use of an output channel. First, the output channel is defined via the `$outchannel` directive:

```
$outchannel log_rotation, /var/log/test_log.log, 104857600, /home/joe/log_rotation_script
```

and then it is used in a rule that selects every syslog message with any priority and executes the previously-defined output channel on the acquired syslog messages:

```
.*.* :omfile:$log_rotation
```

Once the limit (in the example 100 MB) is hit, the `/home/joe/log_rotation_script` is executed. This script can contain anything from moving the file into a different folder, editing specific content out of it, or simply removing it.

**Sending syslog messages to specific users**

`rsyslog` can send syslog messages to specific users by specifying a user name of the user you want to send the messages to (as in Example 21.7, “Specifying Multiple Actions”). To specify more than one user, separate each user name with a comma (,). To send messages to every user that is currently logged on, use an asterisk (*).
Executing a program

`rsyslog` lets you execute a program for selected syslog messages and uses the `system()` call to execute the program in shell. To specify a program to be executed, prefix it with a caret character (^). Consequently, specify a template that formats the received message and passes it to the specified executable as a one line parameter (for more information on templates, see Section 21.2.3, “Templates”).

```
FILTER ^EXECUTABLE; TEMPLATE
```

Here an output of the FILTER condition is processed by a program represented by `EXECUTABLE`. This program can be any valid executable. Replace `TEMPLATE` with the name of the formatting template.

Example 21.6. Executing a Program

In the following example, any syslog message with any priority is selected, formatted with the `template` template and passed as a parameter to the `test-program` program, which is then executed with the provided parameter:

```
*.* ^test-program;template
```

**WARNING**

When accepting messages from any host, and using the shell execute action, you may be vulnerable to command injection. An attacker may try to inject and execute commands in the program you specified to be executed in your action. To avoid any possible security threats, thoroughly consider the use of the shell execute action.

Storing syslog messages in a database

Selected syslog messages can be directly written into a database table using the `database writer` action. The database writer uses the following syntax:

```
PLUGIN : DB_HOST, DB_NAME, DB_USER, DB_PASSWORD ; [TEMPLATE]
```

where:

- The `PLUGIN` calls the specified plug-in that handles the database writing (for example, the `ommysql` plug-in).
- The `DB_HOST` attribute specifies the database host name.
- The `DB_NAME` attribute specifies the name of the database.
- The `DB_USER` attribute specifies the database user.
- The **DB_PASSWORD** attribute specifies the password used with the aforementioned
database user.

- The **TEMPLATE** attribute specifies an optional use of a template that modifies the syslog
message. For more information on templates, see Section 21.2.3, “Templates”.

**IMPORTANT**

Currently, **rsyslog** provides support for **MySQL** and **PostgreSQL** databases only. In
order to use the **MySQL** and **PostgreSQL** database writer functionality, install the
rsyslog-mysql and rsyslog-pgsql packages, respectively. Also, make sure you load
the appropriate modules in your `/etc/rsyslog.conf` configuration file:

```sh
module(load="ommysql")    # Output module for MySQL support
module(load="ompgsql")    # Output module for PostgreSQL support
```

For more information on **rsyslog** modules, see Section 21.6, “Using Rsyslog
Modules”.

Alternatively, you may use a generic database interface provided by the **omlibdb**
module (supports: Firebird/Interbase, MS SQL, Sybase, SQLLite, Ingres, Oracle,
mSQL).

### Discarding syslog messages

To discard your selected messages, use the tilde character (`~`).

```
FILTER ~
```

The discard action is mostly used to filter out messages before carrying on any further processing.
It can be effective if you want to omit some repeating messages that would otherwise fill the log
files. The results of discard action depend on where in the configuration file it is specified, for the
best results place these actions on top of the actions list. Please note that once a message has been
discarded there is no way to retrieve it in later configuration file lines.

For instance, the following rule discards any cron syslog messages:

```
cron.* ~
```

### Specifying Multiple Actions

For each selector, you are allowed to specify multiple actions. To specify multiple actions for one
selector, write each action on a separate line and precede it with an ampersand (`&`) character:

```
FILTER ACTION
& ACTION
& ACTION
```

Specifying multiple actions improves the overall performance of the desired outcome since the
specified selector has to be evaluated only once.

**Example 21.7. Specifying Multiple Actions**
In the following example, all kernel syslog messages with the critical priority (crit) are sent to user user1, processed by the template temp and passed on to the test-program executable, and forwarded to 192.168.0.1 via the UDP protocol.

```
kern.=crit user1 & ^test-program;temp & @192.168.0.1
```

Any action can be followed by a template that formats the message. To specify a template, suffix an action with a semicolon (;) and specify the name of the template. For more information on templates, see Section 21.2.3, “Templates”.

**WARNING**

A template must be defined before it is used in an action, otherwise it is ignored. In other words, template definitions should always precede rule definitions in /etc/rsyslog.conf.

### 21.2.3. Templates

Any output that is generated by rsyslog can be modified and formatted according to your needs with the use of templates. To create a template use the following syntax in /etc/rsyslog.conf:

```
template(name="TEMPLATE_NAME" type="string" string="text %PROPERTY% more text" [option.OPTION="on"])
```

where:

- *template*() is the directive introducing block defining a template.
- The *TEMPLATE_NAME* mandatory argument is used to refer to the template. Note that *TEMPLATE_NAME* should be unique.
- The *type* mandatory argument can acquire one of these values: “list”, “subtree”, “string” or “plugin”.
- The *string* argument is the actual template text. Within this text, special characters, such as \n for newline or \r for carriage return, can be used. Other characters, such as % or ", have to be escaped if you want to use those characters literally. Within this text, special characters, such as \n for new line or \r for carriage return, can be used. Other characters, such as % or ", have to be escaped if you want to use those characters literally.
- The text specified between two percent signs (%) specifies a *property* that allows you to access specific contents of a syslog message. For more information on properties, see the section called “Properties”.
- The *OPTION* attribute specifies any options that modify the template functionality. The currently supported template options are *sql* and *stdsql*, which are used for formatting the
text as an SQL query, or json which formats text to be suitable for JSON processing, and **casesensitive** which sets case sensitiveness of property names.

**NOTE**

Note that the database writer checks whether the `sql` or `stdsql` options are specified in the template. If they are not, the database writer does not perform any action. This is to prevent any possible security threats, such as SQL injection.

See section *Storing syslog messages in a database* in **Section 21.2.2, “Actions”** for more information.

**Generating Dynamic File Names**

Templates can be used to generate dynamic file names. By specifying a property as a part of the file path, a new file will be created for each unique property, which is a convenient way to classify syslog messages.

For example, use the `timegenerated` property, which extracts a time stamp from the message, to generate a unique file name for each syslog message:

```rsyslog
template(name="DynamicFile" type="list") {
  constant(value="/var/log/test_logs/")
  property(name="timegenerated")
  constant(value="-test.log")
}
```

Keep in mind that the `$template` directive only specifies the template. You must use it inside a rule for it to take effect. In `/etc/rsyslog.conf`, use the question mark (`?`) in an action definition to mark the dynamic file name template:

```
*. * ?DynamicFile
```

**Properties**

Properties defined inside a template (between two percent signs (`%`)) enable access various contents of a syslog message through the use of a *property replacer*. To define a property inside a template (between the two quotation marks (`"..."`)), use the following syntax:

```
%PROPERTY_NAME[ :FROM_CHAR:TO_CHAR:OPTION]%
```

where:

- The `PROPERTY_NAME` attribute specifies the name of a property. A list of all available properties and their detailed description can be found in the `rsyslog.conf(5)` manual page under the section *Available Properties*.

- `FROM_CHAR` and `TO_CHAR` attributes denote a range of characters that the specified property will act upon. Alternatively, regular expressions can be used to specify a range of characters. To do so, set the letter `R` as the `FROM_CHAR` attribute and specify your desired regular expression as the `TO_CHAR` attribute.
The `OPTION` attribute specifies any property options, such as the `lowercase` option to convert the input to lowercase. A list of all available property options and their detailed description can be found in the `rsyslog.conf(5)` manual page under the section `Property Options`.

The following are some examples of simple properties:

- The following property obtains the whole message text of a syslog message:

  ```
  %msg%
  ```

- The following property obtains the first two characters of the message text of a syslog message:

  ```
  %msg:1:2%
  ```

- The following property obtains the whole message text of a syslog message and drops its last line feed character:

  ```
  %msg:::drop-last-lf%
  ```

- The following property obtains the first 10 characters of the time stamp that is generated when the syslog message is received and formats it according to the [RFC 3999](https://tools.ietf.org/html/rfc3999) date standard.

  ```
  %timegenerated:1:10:date-rfc3339%
  ```

### Template Examples

This section presents a few examples of `rsyslog` templates.

**Example 21.8, “A verbose syslog message template”** shows a template that formats a syslog message so that it outputs the message's severity, facility, the time stamp of when the message was received, the host name, the message tag, the message text, and ends with a new line.

```
template(name="verbose" type="list") {
  property(name="syslogseverity")
  property(name="syslogfacility")
  property(name="timegenerated")
  property(name="HOSTNAME")
  property(name="syslogtag")
  property(name="msg")
  constant(value="\n")
}
```

**Example 21.9, “A wall message template”** shows a template that resembles a traditional wall message (a message that is send to every user that is logged in and has their `mesg(1)` permission set to `yes`). This template outputs the message text, along with a host name, message tag and a time stamp, on a new line (using \r and \n) and rings the bell (using \7).

```
Example 21.9. A wall message template
```
Example 21.10, “A database formatted message template” shows a template that formats a syslog message so that it can be used as a database query. Notice the use of the sql option at the end of the template specified as the template option. It tells the database writer to format the message as an MySQL SQL query.

Example 21.10. A database formatted message template

```plaintext
template(name="dbFormat" type="list" option.sql="on") {
    constant(value="insert into SystemEvents (Message, Facility, FromHost, Priority, DeviceReportedTime, ReceivedAt, InfoUnitID, SysLogTag)"
    constant(value=" values ('")
    property(name="msg")
    constant(value="', ")
    property(name="syslogfacility")
    constant(value="', ")
    property(name="hostname")
    constant(value="', ")
    property(name="syslogpriority")
    constant(value="', ")
    property(name="timereported" dateFormat="mysql")
    constant(value="', '")
    property(name="timegenerated" dateFormat="mysql")
    constant(value="', '")
    property(name="iut")
    constant(value="', ")
    property(name="syslogtag")
    constant(value="')")
}
```

rsyslog also contains a set of predefined templates identified by the RSYSLOG_prefix. These are reserved for the syslog's use and it is advisable to not create a template using this prefix to avoid conflicts. The following list shows these predefined templates along with their definitions.

**RSYSLOG_DebugFormat**

A special format used for troubleshooting property problems.

```plaintext
template(name="RSYSLOG_DebugFormat" type="string" string="Debug line with all properties:
FROMHOST: '%FROMHOST%', fromhost-ip: '%fromhost-ip%', HOSTNAME: '%HOSTNAME%', PRI: %PRI%, syslogtag '%syslogtag'",
```
RSYSLOG_SyslogProtocol23Format

The format specified in IETF’s internet-draft ietf-syslog-protocol-23, which is assumed to become the new syslog standard RFC.

```perl
template(name="RSYSLOG_SyslogProtocol23Format" type="string"
string="%PRI% %TIMESTAMP:::date-rfc3339% %HOSTNAME% %APP-NAME% %PROCID% %MSGID% %STRUCTURED-DATA% %msg%"
)

RSYSLOG_FileFormat

A modern-style logfile format similar to TraditionalFileFormat, but with high-precision time stamps and time zone information.

```perl
template(name="RSYSLOG_FileFormat" type="list") {
    property(name="timestamp" dateFormat="rfc3339")
    constant(value=" ")
    property(name="hostname")
    constant(value=" ")
    property(name="syslogtag")
    property(name="msg" spifno1stsp="on" )
    property(name="msg" droplastlf="on" )
    constant(value="\n")
}

RSYSLOG_TraditionalFileFormat

The older default log file format with low-precision time stamps.

```perl
template(name="RSYSLOG_TraditionalFileFormat" type="list") {
    property(name="timestamp")
    constant(value=" ")
    property(name="hostname")
    constant(value=" ")
    property(name="syslogtag")
    property(name="msg" spifno1stsp="on" )
    property(name="msg" droplastlf="on" )
    constant(value="\n")
}

RSYSLOG_ForwardFormat

A forwarding format with high-precision time stamps and time zone information.

```perl
template(name="ForwardFormat" type="list") {
    constant(value="<")
    property(name="pri")
    constant(value=">")
    property(name="timestamp" dateFormat="rfc3339")
```
**RSYSLOG TraditionalForwardFormat**

The traditional forwarding format with low-precision time stamps.

```plaintext
template(name="TraditionalForwardFormat" type="list") {
    constant(value="<")
    property(name="pri")
    constant(value=">")
    property(name="timestamp")
    constant(value=" ")
    property(name="hostname")
    constant(value=" ")
    property(name="syslogtag" position.from="1" position.to="32")
    property(name="msg" spifno1stsp="on")
    property(name="msg")
}
```

### 21.2.4. Global Directives

Global directives are configuration options that apply to the `rsyslogd` daemon. They usually specify a value for a specific predefined variable that affects the behavior of the `rsyslogd` daemon or a rule that follows. All of the global directives are enclosed in a `global` configuration block. The following is an example of a global directive that specifies overriding local host name for log messages:

```plaintext
global(localHostname="machineXY")
```

The default size defined for this directive (10,000 messages) can be overridden by specifying a different value (as shown in the example above).

You can define multiple directives in your `/etc/rsyslog.conf` configuration file. A directive affects the behavior of all configuration options until another occurrence of that same directive is detected. Global directives can be used to configure actions, queues and for debugging. A comprehensive list of all available configuration directives can be found in the section called “Online Documentation”. Currently, a new configuration format has been developed that replaces the $-based syntax (see Section 21.3, “Using the New Configuration Format”). However, classic global directives remain supported as a legacy format.

### 21.2.5. Log Rotation

The following is a sample `/etc/logrotate.conf` configuration file:

```plaintext
# rotate log files weekly
weekly
# keep 4 weeks worth of backlogs
```
All of the lines in the sample configuration file define global options that apply to every log file. In our example, log files are rotated weekly, rotated log files are kept for four weeks, and all rotated log files are compressed by gzip into the .gz format. Any lines that begin with a hash sign (#) are comments and are not processed.

You may define configuration options for a specific log file and place it under the global options. However, it is advisable to create a separate configuration file for any specific log file in the /etc/logrotate.d/ directory and define any configuration options there.

The following is an example of a configuration file placed in the /etc/logrotate.d/ directory:

```
/var/log/messages {
    rotate 5
    weekly
    postrotate
        /usr/bin/killall -HUP syslogd
    uncompress
    endscript
}
```

The configuration options in this file are specific for the /var/log/messages log file only. The settings specified here override the global settings where possible. Thus the rotated /var/log/messages log file will be kept for five weeks instead of four weeks as was defined in the global options.

The following is a list of some of the directives you can specify in your logrotate configuration file:

- **weekly** – Specifies the rotation of log files to be done weekly. Similar directives include:
  - daily
  - monthly
  - yearly

- **compress** – Enables compression of rotated log files. Similar directives include:
  - nocompress
  - compresscmd – Specifies the command to be used for compressing.
  - uncompresscmd
  - compressext – Specifies what extension is to be used for compressing.
  - compressoptions – Specifies any options to be passed to the compression program used.
  - delaycompress – Postpones the compression of log files to the next rotation of log files.

- **rotate INTEGER** – Specifies the number of rotations a log file undergoes before it is removed or mailed to a specific address. If the value 0 is specified, old log files are removed instead of rotated.
- **mail ADDRESS** — This option enables mailing of log files that have been rotated as many times as is defined by the `rotate` directive to the specified address. Similar directives include:
  - `nomail`
  - `mailfirst` — Specifies that the just-rotated log files are to be mailed, instead of the about-to-expire log files.
  - `maillast` — Specifies that the about-to-expire log files are to be mailed, instead of the just-rotated log files. This is the default option when `mail` is enabled.

For the full list of directives and various configuration options, see the `logrotate(5)` manual page.

### 21.3. USING THE NEW CONFIGURATION FORMAT

In `rsyslog` version 7, installed by default for Red Hat Enterprise Linux 7 in the `rsyslog` package, a new configuration syntax is introduced. This new configuration format aims to be more powerful, more intuitive, and to prevent common mistakes by not permitting certain invalid constructs. The syntax enhancement is enabled by the new configuration processor that relies on RainerScript. The legacy format is still fully supported and it is used by default in the `/etc/rsyslog.conf` configuration file.

RainerScript is a scripting language designed for processing network events and configuring event processors such as `rsyslog`. RainerScript was first used to define expression-based filters, see **Example 21.3, “Expression-based Filters”**. The version of RainerScript in `rsyslog` version 7 implements the `input()` and `ruleset()` statements, which permit the `/etc/rsyslog.conf` configuration file to be written in the new syntax. The new syntax differs mainly in that it is much more structured; parameters are passed as arguments to statements, such as input, action, template, and module load. The scope of options is limited by blocks. This enhances readability and reduces the number of bugs caused by misconfiguration. There is also a significant performance gain. Some functionality is exposed in both syntaxes, some only in the new one.

Compare the configuration written with legacy-style parameters:

```plaintext
$InputFileName /tmp/inputfile
$InputFileTag tag1:
$InputFileStateFile inputfile-state
$InputRunFileMonitor
```

and the same configuration with the use of the new format statement:

```plaintext
input(type="imfile" file="/tmp/inputfile" tag="tag1:" statefile="inputfile-state")
```

This significantly reduces the number of parameters used in configuration, improves readability, and also provides higher execution speed. For more information on RainerScript statements and parameters see the section called “Online Documentation”.

### 21.3.1. Rulesets

Leaving special directives aside, `rsyslog` handles messages as defined by `rules` that consist of a filter condition and an action to be performed if the condition is true. With a traditionally written `/etc/rsyslog.conf` file, all rules are evaluated in order of appearance for every input message. This process starts with the first rule and continues until all rules have been processed or until the message is discarded by one of the rules.
However, rules can be grouped into sequences called rulesets. With rulesets, you can limit the effect of certain rules only to selected inputs or enhance the performance of rsyslog by defining a distinct set of actions bound to a specific input. In other words, filter conditions that will be inevitably evaluated as false for certain types of messages can be skipped. The legacy ruleset definition in /etc/rsyslog.conf can look as follows:

```
$RuleSet  rulesetname
  rule
  rule2
```

The rule ends when another rule is defined, or the default ruleset is called as follows:

```
$RuleSet  RSYSLOG_DefaultRuleset
```

With the new configuration format in rsyslog 7, the `input()` and `ruleset()` statements are reserved for this operation. The new format ruleset definition in /etc/rsyslog.conf can look as follows:

```
ruleset(name="rulesetname") {
  rule
  rule2
  call rulesetname2
  ...
}
```

Replace `rulesetname` with an identifier for your ruleset. The ruleset name cannot start with `RSYSLOG_` since this namespace is reserved for use by rsyslog. `RSYSLOG_DefaultRuleset` then defines the default set of rules to be performed if the message has no other ruleset assigned. With `rule` and `rule2` you can define rules in filter-action format mentioned above. With the `call` parameter, you can nest rulesets by calling them from inside other ruleset blocks.

After creating a ruleset, you need to specify what input it will apply to:

```
input(type="input_type" port="port_num" ruleset="rulesetname");
```

Here you can identify an input message by `input_type`, which is an input module that gathered the message, or by `port_num` – the port number. Other parameters such as `file` or `tag` can be specified for `input()`. Replace `rulesetname` with a name of the ruleset to be evaluated against the message. In case an input message is not explicitly bound to a ruleset, the default ruleset is triggered.

You can also use the legacy format to define rulesets, for more information see the section called “Online Documentation”.

### Example 21.11. Using rulesets

The following rulesets ensure different handling of remote messages coming from different ports. Add the following into /etc/rsyslog.conf:

```
ruleset(name="remote-6514") {
  action(type="omfile" file="/var/log/remote-6514")
}

ruleset(name="remote-601") {
  cron.* action(type="omfile" file="/var/log/remote-601-cron")
  mail.* action(type="omfile" file="/var/log/remote-601-mail")
```
input(type="imtcp" port="6514" ruleset="remote-6514");
input(type="imtcp" port="601" ruleset="remote-601");

Rulesets shown in the above example define log destinations for the remote input from two ports, in case of port 601, messages are sorted according to the facility. Then, the TCP input is enabled and bound to rulesets. Note that you must load the required modules (imtcp) for this configuration to work.

21.3.2. Compatibility with sysklogd

The compatibility mode specified via the -c option exists in rsyslog version 5 but not in version 7. Also, the sysklogd-style command-line options are deprecated and configuring rsyslog through these command-line options should be avoided. However, you can use several templates and directives to configure rsyslogd to emulate sysklogd-like behavior.

For more information on various rsyslogd options, see the rsyslogd(8) manual page.

21.4. WORKING WITH QUEUES IN RSYSLOG

Queues are used to pass content, mostly syslog messages, between components of rsyslog. With queues, rsyslog is capable of processing multiple messages simultaneously and to apply several actions to a single message at once. The data flow inside rsyslog can be illustrated as follows:

Figure 21.1. Message Flow in Rsyslog

Whenever rsyslog receives a message, it passes this message to the preprocessor and then places it into the main message queue. Messages wait there to be dequeued and passed to the rule processor.

The rule processor is a parsing and filtering engine. Here, the rules defined in /etc/rsyslog.conf are applied. Based on these rules, the rule processor evaluates which actions are to be performed. Each action has its own action queue. Messages are passed through this queue to the respective action.
processor which creates the final output. Note that at this point, several actions can run simultaneously on one message. For this purpose, a message is duplicated and passed to multiple action processors.

Only one queue per action is possible. Depending on configuration, the messages can be sent right to the action processor without action queuing. This is the behavior of direct queues (see below). In case the output action fails, the action processor notifies the action queue, which then takes an unprocessed element back and after some time interval, the action is attempted again.

To sum up, there are two positions where queues stand in rsyslog: either in front of the rule processor as a single main message queue or in front of various types of output actions as action queues. Queues provide two main advantages that both lead to increased performance of message processing:

- they serve as buffers that decouple producers and consumers in the structure of rsyslog
- they allow for parallelization of actions performed on messages

Apart from this, queues can be configured with several directives to provide optimal performance for your system. These configuration options are covered in the following sections.

**WARNING**

If an output plug-in is unable to deliver a message, it is stored in the preceding message queue. If the queue fills, the inputs block until it is no longer full. This will prevent new messages from being logged via the blocked queue. In the absence of separate action queues this can have severe consequences, such as preventing SSH logging, which in turn can prevent SSH access. Therefore it is advised to use dedicated action queues for outputs which are forwarded over a network or to a database.

### 21.4.1. Defining Queues

Based on where the messages are stored, there are several types of queues: direct, in-memory, disk, and disk-assisted in-memory queues that are most widely used. You can choose one of these types for the main message queue and also for action queues. Add the following into `/etc/rsyslog.conf`:

```conf
object(queue.type="queue_type")
```

By adding this you can apply the setting for:

- main message queue: replace `object` with `main_queue`
- an action queue: replace `object` with `action`
- ruleset: replace `object` with `ruleset`

Replace `queue_type` with one of `direct`, `linkedlist` or `fixedarray` (which are in-memory queues), or `disk`.

The default setting for a main message queue is the FixedArray queue with a limit of 10,000 messages. Action queues are by default set as Direct queues.
**Direct Queues**
For many simple operations, such as when writing output to a local file, building a queue in front of an action is not needed. To avoid queuing, use:

```
object(queue.type="Direct")
```

Replace `object` with `main_queue`, `action` or `ruleset` to use this option to the main message queue, an action queue or for the ruleset respectively. With direct queue, messages are passed directly and immediately from the producer to the consumer.

**Disk Queues**
Disk queues store messages strictly on a hard drive, which makes them highly reliable but also the slowest of all possible queuing modes. This mode can be used to prevent the loss of highly important log data. However, disk queues are not recommended in most use cases. To set a disk queue, type the following into `/etc/rsyslog.conf`:

```
object(queue.type="Disk")
```

Replace `object` with `main_queue`, `action` or `ruleset` to use this option to the main message queue, an action queue or for the ruleset respectively. Disk queues are written in parts, with a default size 10 Mb. This default size can be modified with the following configuration directive:

```
object(queue.size="size")
```

where `size` represents the specified size of disk queue part. The defined size limit is not restrictive, `rsyslog` always writes one complete queue entry, even if it violates the size limit. Each part of a disk queue matches with an individual file. The naming directive for these files looks as follows:

```
object(queue.filename="name")
```

This sets a `name` prefix for the file followed by a 7-digit number starting at one and incremented for each file.

**In-memory Queues**
With in-memory queue, the enqueued messages are held in memory which makes the process very fast. The queued data is lost if the computer is power cycled or shut down. However, you can use the `action (queue.saveonshutdown="on")` setting to save the data before shutdown. There are two types of in-memory queues:

- **FixedArray** queue — the default mode for the main message queue, with a limit of 10,000 elements. This type of queue uses a fixed, pre-allocated array that holds pointers to queue elements. Due to these pointers, even if the queue is empty a certain amount of memory is consumed. However, FixedArray offers the best run time performance and is optimal when you expect a relatively low number of queued messages and high performance.

- **LinkedList** queue — here, all structures are dynamically allocated in a linked list, thus the memory is allocated only when needed. LinkedList queues handle occasional message bursts very well.

In general, use LinkedList queues when in doubt. Compared to FixedArray, it consumes less memory and lowers the processing overhead.

Use the following syntax to configure in-memory queues:

```
Disk-Assisted In-memory Queues

Both disk and in-memory queues have their advantages and rsyslog lets you combine them in disk-assisted in-memory queues. To do so, configure a normal in-memory queue and then add the `queue.filename="file_name"` directive to its block to define a file name for disk assistance. This queue then becomes disk-assisted, which means it couples an in-memory queue with a disk queue to work in tandem.

The disk queue is activated if the in-memory queue is full or needs to persist after shutdown. With a disk-assisted queue, you can set both disk-specific and in-memory specific configuration parameters. This type of queue is probably the most commonly used, it is especially useful for potentially long-running and unreliable actions.

To specify the functioning of a disk-assisted in-memory queue, use the so-called watermarks:

```plaintext
object(queue.highwatermark="number")
object(queue.lowwatermark="number")
```

Example 21.12. Reliable Forwarding of Log Messages to a Server

Rsyslog is often used to maintain a centralized logging system, where log messages are forwarded to a server over the network. To avoid message loss when the server is not available, it is advisable to configure an action queue for the forwarding action. This way, messages that failed to be sent are stored locally until the server is reachable again. Note that such queues are not configurable for connections using the UDP protocol.

Procedure 21.1. Forwarding To a Single Server

Suppose the task is to forward log messages from the system to a server with host name `example.com`, and to configure an action queue to buffer the messages in case of a server outage. To do so, perform the following steps:

- Use the following configuration in `/etc/rsyslog.conf` or create a file with the following content in the `/etc/rsyslog.d/` directory:

  ```
  *. action(type="omfwd"
  queue.type="LinkedList"
  ```
Where:

- **queue.type** enables a LinkedList in-memory queue,
- **queue.filename** defines a disk storage, in this case the backup files are created in the /var/lib/rsyslog/ directory with the example_fwd prefix,
- the **action.resumeRetryCount= "-1"** setting prevents rsyslog from dropping messages when retrying to connect if server is not responding,
- **queue.saveonshutdown** saves in-memory data if rsyslog shuts down,
- the last line forwards all received messages to the logging server using reliable TCP delivery, port specification is optional.

With the above configuration, rsyslog keeps messages in memory if the remote server is not reachable. A file on disk is created only if rsyslog runs out of the configured memory queue space or needs to shut down, which benefits the system performance.

**Procedure 21.2. Forwarding To Multiple Servers**

The process of forwarding log messages to multiple servers is similar to the previous procedure:

- Each destination server requires a separate forwarding rule, action queue specification, and backup file on disk. For example, use the following configuration in /etc/rsyslog.conf or create a file with the following content in the /etc/rsyslog.d/ directory:

```plaintext
*.* action(type="omfwd"
  queue.type="LinkedList"
  queue.filename="example_fwd1"
  action.resumeRetryCount="-1"
  queue.saveonshutdown="on"
  Target="example1.com" Protocol="tcp")

*.* action(type="omfwd"
  queue.type="LinkedList"
  queue.filename="example_fwd2"
  action.resumeRetryCount="-1"
  queue.saveonshutdown="on"
  Target="example2.com" Protocol="tcp")
```

**21.4.2. Creating a New Directory for rsyslog Log Files**

Rsyslog runs as the syslogd daemon and is managed by SELinux. Therefore all files to which rsyslog is required to write to, must have the appropriate SELinux file context.

**Procedure 21.3. Creating a New Working Directory**

1. If required to use a different directory to store working files, create a directory as follows:
2. Install utilities to manage SELinux policy:

```bash
~# mkdir /rsyslog
```

3. Set the SELinux directory context type to be the same as the /var/lib/rsyslog/ directory:

```bash
~# semanage fcontext -a -t syslogd_var_lib_t /rsyslog
```

4. Apply the SELinux context:

```bash
~# restorecon -R -v /rsyslog
restorecon reset /rsyslog
type:unconfined_u:object_r:syslogd_var_lib_t:s0
```

5. If required, check the SELinux context as follows:

```bash
~# ls -Zd /rsyslog
drwxr-xr-x. root root system_u:object_r:syslogd_var_lib_t:s0
```

6. Create subdirectories as required. For example:

```bash
~# mkdir /rsyslog/work/
```

The subdirectories will be created with the same SELinux context as the parent directory.

7. Add the following line in /etc/rsyslog.conf immediately before it is required to take effect:

```bash
global(workDirectory="/rsyslog/work")
```

This setting will remain in effect until the next WorkDirectory directive is encountered while parsing the configuration files.

## 21.4.3. Managing Queues

All types of queues can be further configured to match your requirements. You can use several directives to modify both action queues and the main message queue. Currently, there are more than 20 queue parameters available, see the section called “Online Documentation”. Some of these settings are used commonly, others, such as worker thread management, provide closer control over the queue behavior and are reserved for advanced users. With advanced settings, you can optimize rsyslog’s performance, schedule queuing, or modify the behavior of a queue on system shutdown.

### Limiting Queue Size

You can limit the number of messages that queue can contain with the following setting:

```bash
object(queue.highwatermark="number")
```

Replace object with main_queue, action or ruleset to use this option to the main message queue, an action queue or for the ruleset respectively. Replace number with a number of enqueued messages.
You can set the queue size only as the number of messages, not as their actual memory size. The default queue size is 10,000 messages for the main message queue and ruleset queues, and 1000 for action queues.

Disk assisted queues are unlimited by default and can not be restricted with this directive, but you can reserve them physical disk space in bytes with the following settings:

\[
\text{object(queue.maxdiskspace=\textquoteright\texttt{number}\textquoteright)}
\]

Replace `object` with `main_queue`, `action` or `ruleset`. When the size limit specified by `number` is hit, messages are discarded until sufficient amount of space is freed by dequeued messages.

**Discarding Messages**

When a queue reaches a certain number of messages, you can discard less important messages in order to save space in the queue for entries of higher priority. The threshold that launches the discarding process can be set with the so-called `discard mark`:

\[
\text{object(queue.discardmark=\textquoteright\texttt{number}\textquoteright)}
\]

Replace `object` with `MainMsg` or with `Action` to use this option to the main message queue or for an action queue respectively. Here, `number` stands for a number of messages that have to be in the queue to start the discarding process. To define which messages to discard, use:

\[
\text{object(queue.discardseverity=\textquoteright\texttt{number}\textquoteright)}
\]

Replace `number` with one of the following numbers for respective priorities: 7 (debug), 6 (info), 5 (notice), 4 (warning), 3 (err), 2 (crit), 1 (alert), or 0 (emerg). With this setting, both newly incoming and already queued messages with lower than defined priority are erased from the queue immediately after the discard mark is reached.

**Using Timeframes**

You can configure `rsyslog` to process queues during a specific time period. With this option you can, for example, transfer some processing into off-peak hours. To define a time frame, use the following syntax:

\[
\text{object(queue.dequeuetimebegin=\textquoteright\texttt{hour}\textquoteright)}
\]

\[
\text{object(queue.dequeuetimeend=\textquoteright\texttt{hour}\textquoteright)}
\]

With `hour` you can specify hours that bound your time frame. Use the 24-hour format without minutes.

**Configuring Worker Threads**

A `worker thread` performs a specified action on the enqueued message. For example, in the main message queue, a worker task is to apply filter logic to each incoming message and enqueue them to the relevant action queues. When a message arrives, a worker thread is started automatically. When the number of messages reaches a certain number, another worker thread is turned on. To specify this number, use:

\[
\text{object(queue.workerthreadminimummessages=\textquoteright\texttt{number}\textquoteright)}
\]

Replace `number` with a number of messages that will trigger a supplemental worker thread. For example, with `number` set to 100, a new worker thread is started when more than 100 messages arrive. When more than 200 messages arrive, the third worker thread starts and so on. However, too many
working threads running in parallel becomes ineffective, so you can limit the maximum number of them by using:

```object(queue.workerthreads="number")
```

where `number` stands for a maximum number of working threads that can run in parallel. For the main message queue, the default limit is 1 thread. Once a working thread has been started, it keeps running until an inactivity timeout appears. To set the length of timeout, type:

```object(queue.timeoutworkerthreadshutdown="time")
```

Replace `time` with the duration set in milliseconds. Specifies time without new messages after which the worker thread will be closed. Default setting is one minute.

**Batch Dequeuing**
To increase performance, you can configure `rsyslog` to dequeue multiple messages at once. To set the upper limit for such dequeuing, use:

```$object(queue.DequeueBatchSize="number")
```

Replace `number` with the maximum number of messages that can be dequeued at once. Note that a higher setting combined with a higher number of permitted working threads results in greater memory consumption.

**Terminating Queues**
When terminating a queue that still contains messages, you can try to minimize the data loss by specifying a time interval for worker threads to finish the queue processing:

```object(queue.timeoutshutdown="time")
```

Specify `time` in milliseconds. If after that period there are still some enqueued messages, workers finish the current data element and then terminate. Unprocessed messages are therefore lost. Another time interval can be set for workers to finish the final element:

```object(queue.timeoutactioncompletion="time")
```

In case this timeout expires, any remaining workers are shut down. To save data at shutdown, use:

```object(queue.saveonshutdown="on")
```

If set, all queue elements are saved to disk before `rsyslog` terminates.

### 21.4.4. Using the New Syntax for `rsyslog` queues

In the new syntax available in `rsyslog` 7, queues are defined inside the `action()` object that can be used both separately or inside a ruleset in `/etc/rsyslog.conf`. The format of an action queue is as follows:

```action(type="action_type" queue.size="queue_size" queue.type="queue_type" queue.filename="file_name")
```

Replace `action_type` with the name of the module that is to perform the action and replace `queue_size` with a maximum number of messages the queue can contain. For `queue_type`, choose `disk` or select
from one of the in-memory queues: direct, linkedlist or fixedarray. For file_name specify only a file name, not a path. Note that if creating a new directory to hold log files, the SELinux context must be set. See Section 21.4.2, “Creating a New Directory for rsyslog Log Files” for an example.

**Example 21.13. Defining an Action Queue**

To configure the output action with an asynchronous linked-list based action queue which can hold a maximum of 10,000 messages, enter a command as follows:

```
action(type="omfile" queue.size="10000" queue.type="linkedlist" queue.filename="logfile")
```

The rsyslog 7 syntax for a direct action queues is as follows:

```
*. action(type="omfile" file="/var/lib/rsyslog/log_file")
```

The rsyslog 7 syntax for an action queue with multiple parameters can be written as follows:

```
*. action(type="omfile"
    queue.filename="log_file"
    queue.type="linkedlist"
    queue.size="10000"
)
```

The default work directory, or the last work directory to be set, will be used. If required to use a different work directory, add a line as follows before the action queue:

```
global(workDirectory="/directory")
```

**Example 21.14. Forwarding To a Single Server Using the New Syntax**

The following example is based on the procedure Procedure 21.1, “Forwarding To a Single Server” in order to show the difference between the traditional syntax and the rsyslog 7 syntax. The omfwd plug-in is used to provide forwarding over UDP or TCP. The default is UDP. As the plug-in is built in it does not have to be loaded.

Use the following configuration in `/etc/rsyslog.conf` or create a file with the following content in the `/etc/rsyslog.d/` directory:

```
*. action(type="omfwd"
    queue.type="linkedlist"
    queue.filename="example_fwd"
    action.resumeRetryCount="-1"
    queue.saveOnShutdown="on"
    target="example.com" port="6514" protocol="tcp"
)
```

Where:

- `queue.type="linkedlist"` enables a LinkedList in-memory queue,
- `queue.filename` defines a disk storage. The backup files are created with the
The \texttt{rsyslog} service provides facilities both for running a logging server and for configuring individual systems to send their log files to the logging server. See \texttt{Example 21.12, "Reliable Forwarding of Log Messages to a Server"} for information on client \texttt{rsyslog} configuration.

The \texttt{rsyslog} service must be installed on the system that you intend to use as a logging server and all systems that will be configured to send logs to it. Rsyslog is installed by default in Red Hat Enterprise Linux 7. If required, to ensure that it is, enter the following command as \texttt{root}:

\begin{verbatim}
-]# yum install rsyslog
\end{verbatim}

The default protocol and port for syslog traffic is \texttt{UDP} and 514, as listed in the \texttt{/etc/services} file. However, \texttt{rsyslog} defaults to using \texttt{TCP} on port 514. In the configuration file, \texttt{/etc/rsyslog.conf}, \texttt{TCP} is indicated by \texttt{@@}.

Other ports are sometimes used in examples, however SELinux is only configured to allow sending and receiving on the following ports by default:

\begin{verbatim}
-]# semanage port -l | grep syslog
syslogd_port_t tcp 6514, 601
syslogd_port_t udp 514, 6514, 601
\end{verbatim}

The \texttt{semanage} utility is provided as part of the \texttt{policycoreutils-python} package. If required, install the package as follows:

\begin{verbatim}
-]# yum install policycoreutils-python
\end{verbatim}

In addition, by default the SELinux type for \texttt{rsyslog}, \texttt{rsyslogd_t}, is configured to permit sending and receiving to the remote shell (\texttt{rsh}) port with SELinux type \texttt{rsh_port_t}, which defaults to \texttt{TCP} on port 514. Therefore it is not necessary to use \texttt{semanage} to explicitly permit \texttt{TCP} on port 514. For example, to check what SELinux is set to permit on port 514, enter a command as follows:

\begin{verbatim}
-]# semanage port -l | grep 514
\end{verbatim}

\begin{verbatim}
output omitted
rsh_port_t tcp 514
syslogd_port_t tcp 6514, 601
syslogd_port_t udp 514, 6514, 601
\end{verbatim}

For more information on SELinux, see \textit{Red Hat Enterprise Linux 7 SELinux User's and Administrator's Guide}. 
Perform the steps in the following procedures on the system that you intend to use as your logging server. All steps in these procedure must be made as the root user.

**Procedure 21.4. Configure SELinux to Permit rsyslog Traffic on a Port**

If required to use a new port for rsyslog traffic, follow this procedure on the logging server and the clients. For example, to send and receive TCP traffic on port 10514, proceed as follows:

1. ~]# `semanage port -a -t syslogd_port_t -p tcp 10514`
2. Review the SELinux ports by entering the following command:
   ~]# `semanage port -l | grep syslog`
3. If the new port was already configured in `/etc/rsyslog.conf`, restart rsyslog now for the change to take effect:
   ~]# `service rsyslog restart`
4. Verify which ports rsyslog is now listening to:
   ~]# `netstat -tnlp | grep rsyslog`

   ```
   tcp        0      0 0.0.0.0:10514 0.0.0.0:*   LISTEN
   2528/rsyslogd
   tcp        0      0 ::10514                :::*        LISTEN
   2528/rsyslogd
   ```

   See the `semanage-port(8)` manual page for more information on the `semanage port` command.

**Procedure 21.5. Configuring firewalld**

Configure firewalld to allow incoming rsyslog traffic. For example, to allow TCP traffic on port 10514, proceed as follows:

1. ~]# `firewall-cmd --zone=zone --add-port=10514/tcp`
   success

   Where zone is the zone of the interface to use. Note that these changes will not persist after the next system start. To make permanent changes to the firewall, repeat the commands adding the `--permanent` option. For more information on opening and closing ports in firewalld, see the Red Hat Enterprise Linux 7 Security Guide.

2. To verify the above settings, use a command as follows:

   ```
   ~]# firewall-cmd --list-all
   public (default, active)
   interfaces: eth0
   sources:
   services: dhcpv6-client ssh
   ports: 10514/tcp
   masquerade: no
   ```

1. Open the `/etc/rsyslog.conf` file in a text editor and proceed as follows:
   a. Add these lines below the modules section but above the `Provides UDP syslog reception` section:

   ```
   # Define templates before the rules that use them
   
   ### Per-Host Templates for Remote Systems ###
   $template TmplAuthpriv,
   
   
   
   /var/log/remote/auth/%HOSTNAME%/%PROGRAMNAME:::secpath-replace%.log"
   $template TmplMsg,
   
   
   /var/log/remote/msg/%HOSTNAME%/%PROGRAMNAME:::secpath-replace%.log"
   
   b. Replace the default `Provides TCP syslog reception` section with the following:

   ```
   # Provides TCP syslog reception
   $ModLoad imtcp
   
   # Adding this ruleset to process remote messages
   $RuleSet remote1
   
   authpriv.*   ?TmplAuthpriv
   *.info;mail.none;authpriv.none;cron.none   ?TmplMsg
   
   $RuleSet RSYSLOG_DefaultRuleset   #End the rule set by switching back to the default rule set
   
   $InputTCPServerBindRuleset remote1  #Define a new input and bind it to the "remote1" rule set
   $InputTCPServerRun 10514
   
   Save the changes to the `/etc/rsyslog.conf` file.
   
   2. The `rsyslog` service must be running on both the logging server and the systems attempting to log to it.
   a. Use the `systemctl` command to start the `rsyslog` service.

   ```
   -]# systemctl start rsyslog
   
   b. To ensure the `rsyslog` service starts automatically in future, enter the following command as root:

   ```
   -]# systemctl enable rsyslog
   
   Your log server is now configured to receive and store log files from the other systems in your environment.

Rsyslog 7 has a number of different templates styles. The string template most closely resembles the legacy format. Reproducing the templates from the example above using the string format would look as follows:

```
template(name="TmplAuthpriv" type="string"
    string="/var/log/remote/auth/%HOSTNAME%/%PROGRAMNAME:::secpath-replace%.log"
)

template(name="TmplMsg" type="string"
    string="/var/log/remote/msg/%HOSTNAME%/%PROGRAMNAME:::secpath-replace%.log"
)
```

These templates can also be written in the list format as follows:

```
template(name="TmplAuthpriv" type="list") {
    constant(value="/var/log/remote/auth/")
    property(name="hostname")
    constant(value="/"
    property(name="programname" SecurePath="replace")
    constant(value=".log")
}

template(name="TmplMsg" type="list") {
    constant(value="/var/log/remote/msg/")
    property(name="hostname")
    constant(value="/"
    property(name="programname" SecurePath="replace")
    constant(value=".log")
}
```

This template text format might be easier to read for those new to rsyslog and therefore can be easier to adapt as requirements change.

To complete the change to the new syntax, we need to reproduce the module load command, add a rule set, and then bind the rule set to the protocol, port, and ruleset:

```
module(load="imtcp")

ruleset(name="remote1"){
    authpriv.*   action(type="omfile" DynaFile="TmplAuthpriv")
    *.info;mail.none;authpriv.none;cron.none action(type="omfile" DynaFile="TmplMsg")
}

input(type="imtcp" port="10514" ruleset="remote1")
```

21.6. USING RSYSLOG MODULES

Due to its modular design, rsyslog offers a variety of modules which provide additional functionality. Note that modules can be written by third parties. Most modules provide additional inputs (see Input
Modules below) or outputs (see Output Modules below). Other modules provide special functionality specific to each module. The modules may provide additional configuration directives that become available after a module is loaded. To load a module, use the following syntax:

```bash
module(load="MODULE")
```

where `MODULE` represents your desired module. For example, if you want to load the Text File Input Module (`imfile`) that enables `rsyslog` to convert any standard text files into syslog messages, specify the following line in the `/etc/rsyslog.conf` configuration file:

```bash
module(load="imfile")
```

`rsyslog` offers a number of modules which are split into the following main categories:

- **Input Modules** — Input modules gather messages from various sources. The name of an input module always starts with the `im` prefix, such as `imfile` and `imjournal`.

- **Output Modules** — Output modules provide a facility to issue message to various targets such as sending across a network, storing in a database, or encrypting. The name of an output module always starts with the `om` prefix, such as `omsnmp`, `omrelp`, and so on.

- **Parser Modules** — These modules are useful in creating custom parsing rules or to parse malformed messages. With moderate knowledge of the C programming language, you can create your own message parser. The name of a parser module always starts with the `pm` prefix, such as `pmrfc5424`, `pmrfc3164`, and so on.

- **Message Modification Modules** — Message modification modules change content of syslog messages. Names of these modules start with the `mm` prefix. Message Modification Modules such as `mmanon`, `mmnormalize`, or `mmjsonparse` are used for anonymization or normalization of messages.

- **String Generator Modules** — String generator modules generate strings based on the message content and strongly cooperate with the template feature provided by `rsyslog`. For more information on templates, see Section 21.2.3, “Templates”. The name of a string generator module always starts with the `sm` prefix, such as `smfile` or `smtradfile`.

- **Library Modules** — Library modules provide functionality for other loadable modules. These modules are loaded automatically by `rsyslog` when needed and cannot be configured by the user.

A comprehensive list of all available modules and their detailed description can be found at [http://www.rsyslog.com/doc/rsyslog_conf_modules.html](http://www.rsyslog.com/doc/rsyslog_conf_modules.html).

**WARNING**

Note that when `rsyslog` loads any modules, it provides them with access to some of its functions and data. This poses a possible security threat. To minimize security risks, use trustworthy modules only.

### 21.6.1. Importing Text Files
The Text File Input Module, abbreviated as \texttt{imfile}, enables \texttt{rsyslog} to convert any text file into a stream of syslog messages. You can use \texttt{imfile} to import log messages from applications that create their own text file logs. To load \texttt{imfile}, add the following into \texttt{/etc/rsyslog.conf}:

\begin{verbatim}
module(load="imfile"
       PollingInterval="int")
\end{verbatim}

It is sufficient to load \texttt{imfile} once, even when importing multiple files. The \texttt{PollingInterval} module argument specifies how often \texttt{rsyslog} checks for changes in connected text files. The default interval is 10 seconds, to change it, replace \texttt{int} with a time interval specified in seconds.

To identify the text files to import, use the following syntax in \texttt{/etc/rsyslog.conf}:

\begin{verbatim}
# File 1
input(type="imfile"
      File="path_to_file"
      Tag="tag:
      Severity="severity"
      Facility="facility")

# File 2
input(type="imfile"
      File="path_to_file2")
... 
\end{verbatim}

Settings required to specify an input text file:

- replace \texttt{path_to_file} with a path to the text file.
- replace \texttt{tag:} with a tag name for this message.

Apart from the required directives, there are several other settings that can be applied on the text input. Set the severity of imported messages by replacing \texttt{severity} with an appropriate keyword. Replace \texttt{facility} with a keyword to define the subsystem that produced the message. The keywords for severity and facility are the same as those used in facility/priority-based filters, see Section 21.2.1, “Filters”.

Example 21.15. Importing Text Files

The Apache HTTP server creates log files in text format. To apply the processing capabilities of \texttt{rsyslog} to apache error messages, first use the \texttt{imfile} module to import the messages. Add the following into \texttt{/etc/rsyslog.conf}:

\begin{verbatim}
module(load="imfile")
input(type="imfile"
      File="/var/log/httpd/error_log"
      Tag="apache-error:")
\end{verbatim}

21.6.2. Exporting Messages to a Database

Processing of log data can be faster and more convenient when performed in a database rather than with text files. Based on the type of DBMS used, choose from various output modules such as \texttt{ommysql}, \texttt{ompgsql}, \texttt{omoracle}, or \texttt{ommongodb}. As an alternative, use the generic \texttt{omlibdbi output}
module that relies on the libdbi library. The omlibdbi module supports database systems Firebird/Interbase, MS SQL, Sybase, SQLite, Ingres, Oracle, mSQL, MySQL, and PostgreSQL.

Example 21.16. Exporting Rsyslog Messages to a Database

To store the rsyslog messages in a MySQL database, add the following into /etc/rsyslog.conf:

```
module(load="ommysql")
*.  action(type"ommysql"
server="database-server"
  db="database-name"
  uid="database-userid"
  pwd="database-password"
  serverport="1234")
```

First, the output module is loaded, then the communication port is specified. Additional information, such as name of the server and the database, and authentication data, is specified on the last line of the above example.

21.6.3. Enabling Encrypted Transport

Confidentiality and integrity in network transmissions can be provided by either the TLS or GSSAPI encryption protocol.

Transport Layer Security (TLS) is a cryptographic protocol designed to provide communication security over the network. When using TLS, rsyslog messages are encrypted before sending, and mutual authentication exists between the sender and receiver. For configuring TLS, see the section called “Configuring Encrypted Message Transfer with TLS”.

Generic Security Service API (GSSAPI) is an application programming interface for programs to access security services. To use it in connection with rsyslog you must have a functioning Kerberos environment. For configuring GSSAPI, see the section called “Configuring Encrypted Message Transfer with GSSAPI”.

Configuring Encrypted Message Transfer with TLS

To use encrypted transport through TLS, you need to configure both the server and the client.

1. Create public key, private key and certificate file, see Section 13.1.11, “Generating a New Key and Certificate”.

2. On the server side, configure the following in the /etc/rsyslog.conf configuration file:

   a. Set the gtls netstream driver as the default driver:

      ```
      global(defaultnetstreamdriver="gtls")
      ```

   b. Provide paths to certificate files:

      ```
      global(defaultnetstreamdrivercafile="path_ca.pem"
        defaultnetstreamdrivercertfile="path_cert.pem"
        defaultnetstreamdriverkeyfile="path_key.pem")
      ```
You can merge all global directives into single block if you prefer a less cluttered configuration file.

Replace:
- `path_ca.pem` with a path to your public key
- `path_cert.pem` with a path to the certificate file
- `path_key.pem` with a path to the private key

c. Load the `imtcp` module and set driver options:

```plaintext
module(load="imtcp"
StreamDriver.Mode="number"
StreamDriver.AuthMode="anon")
```

d. Start a server:

```plaintext
input(type="imtcp" port="port")
```

Replace:
- `number` to specify the driver mode. To enable TCP-only mode, use 1
- `port` with the port number at which to start a listener, for example 10514

The `anon` setting means that the client is not authenticated.

3. On the client side, configure the following in the `/etc/rsyslog.conf` configuration file:

a. Load the public key:

```plaintext
global(defaultnetstreamdrivercafile="path_ca.pem")
```

Replace `path_ca.pem` with a path to the public key.

b. Set the `gtls` netstream driver as the default driver:

```plaintext
global(defaultnetstreamdriver="gtls")
```

c. Configure the driver and specify what action will be performed:

```plaintext
module(load="imtcp"
  streamdrivermode="number"
  streamdriverauthmode="anon")
input(type="imtcp"
  address="server.net"
  port="port")
```

Replace `number`, `anon`, and `port` with the same values as on the server.

On the last line in the above listing, an example action forwards messages from the server to the specified TCP port.
Configuring Encrypted Message Transfer with GSSAPI

In rsyslog, interaction with GSSAPI is provided by the `imgssapi` module. To turn on the GSSAPI transfer mode:

1. Put the following configuration in `/etc/rsyslog.conf`:

   ```
   $ModLoad imgssapi
   ```

   This directive loads the imgssapi module.

2. Specify the input as follows:

   ```
   $InputGSSServerServiceName name
   $InputGSSServerPermitPlainTCP on
   $InputGSSServerMaxSessions number
   $InputGSSServerRun port
   ```

   - Replace `name` with the name of the GSS server.
   - Replace `number` to set the maximum number of sessions supported. This number is not limited by default.
   - Replace `port` with a selected port on which you want to start a GSS server.

   The `$InputGSSServerPermitPlainTCP on` setting permits the server to receive also plain TCP messages on the same port. This is off by default.

   **NOTE**

   The `imgssapi` module is initialized as soon as the configuration file reader encounters the `$InputGSSServerRun` directive in the `/etc/rsyslog.conf` configuration file. The supplementary options configured after `$InputGSSServerRun` are therefore ignored. For configuration to take effect, all imgssapi configuration options must be placed before `$InputGSSServerRun`.

**Example 21.17. Using GSSAPI**

The following configuration enables a GSS server on the port 1514 that also permits to receive plain TCP syslog messages on the same port.

```
$ModLoad imgssapi
$InputGSSServerPermitPlainTCP on
$InputGSSServerRun 1514
```

**21.6.4. Using RELP**

Reliable Event Logging Protocol (RELP) is a networking protocol for data logging in computer networks. It is designed to provide reliable delivery of event messages, which makes it useful in environments where message loss is not acceptable.

**Configuring RELP**
To configure RELP, you need to configure both the server and the client using the `/etc/rsyslog.conf` file.

1. To configure the client:
   a. Load the required modules:
   ```
   module(load="imuxsock")
   module(load="omrelp")
   module(load="imtcp")
   ```
   b. Configure the TCP input as follows:
   ```
   input(type="imtcp" port="port")
   ```
   Replace `port` to start a listener at the required port.
   c. Configure the transport settings:
   ```
   action(type="omrelp" target="target_IP" port="target_port")
   ```
   Replace `target_IP` and `target_port` with the IP address and port that identify the target server.

2. To configure the server:
   a. Configure loading the module:
   ```
   module(load="imuxsock")
   module(load="imrelp" ruleset="relp")
   ```
   b. Configure the TCP input similarly to the client configuration:
   ```
   input(type="imrelp" port="target_port")
   ```
   Replace `target_port` with the same value as on the clients.
   c. Configure the rules and choose an action to be performed. In the following example, `log_path` specifies the path for storing messages:
   ```
   ruleset (name="relp") {
   action(type="omfile" file="log_path")
   }
   ```

Configuring RELP with TLS

To configure RELP with TLS, you need to configure authentication. Then, you need to configure both the server and the client using the `/etc/rsyslog.conf` file.

1. Create public key, private key and certificate file. For instructions, see Section 13.1.11, “Generating a New Key and Certificate”.

2. To configure the client:
   a. Load the required modules:
b. Configure the TCP input as follows:

```
input(type="imtcp" port="port")
```

Replace `port` to start a listener at the required port.

c. Configure the transport settings:

```
action(type="omrelp" target="target_IP" port="target_port"
  tls="on"
  tls.caCert="path_ca.pem"
  tls.myCert="path_cert.pem"
  tls.myPrivKey="path_key.pem"
  tls.authmode="mode"
  tls.permittedpeer=["peer_name"]
)
```

Replace:

- `target_IP` and `target_port` with the IP address and port that identify the target server.
- `path_ca.pem`, `path_cert.pem`, and `path_key.pem` with paths to the certification files
- `mode` with the authentication mode for the transaction. Use either "name" or "fingerprint"
- `peer_name` with a certificate fingerprint of the permitted peer. If you specify this, `tls.permittedpeer` restricts connection to the selected group of peers.

The `tls="on"` setting enables the TLS protocol.

3. To configure the server:

a. Configure loading the module:

```
module(load="imuxsock")
module(load="imrelp")
module(load="imtcp")
```

b. Configure the TCP input similarly to the client configuration:

```
input(type="imrelp" port="target_port" tls="on"
  tls.caCert="path_ca.pem"
  tls.myCert="path_cert.pem"
  tls.myPrivKey="path_key.pem"
  tls.authmode="name"
  tls.permittedpeer=["peer_name","peer_name1","peer_name2"]
)
```

Replace the highlighted values with the same as on the client.
c. Configure the rules and choose an action to be performed. In the following example, `log_path` specifies the path for storing messages:

```conf
ruleset (name="relp") {
  action(type="omfile" file="log_path")
}
```

### 21.7. INTERACTION OF RSYSLOG AND JOURNAL

As mentioned above, **Rsyslog** and **Journal**, the two logging applications present on your system, have several distinctive features that make them suitable for specific use cases. In many situations it is useful to combine their capabilities, for example to create structured messages and store them in a file database (see [Section 21.8, “Structured Logging with Rsyslog”](#)). A communication interface needed for this cooperation is provided by input and output modules on the side of **Rsyslog** and by the **Journal**'s communication socket.

By default, `rsyslogd` uses the `imjournal` module as a default input mode for journal files. With this module, you import not only the messages but also the structured data provided by `journald`. Also, older data can be imported from `journald` (unless forbidden with the `IgnorePreviousMessages` option). See [Section 21.8.1, “Importing Data from Journal”](#) for basic configuration of `imjournal`.

As an alternative, configure `rsyslogd` to read from the socket provided by `journal` as an output for syslog-based applications. The path to the socket is `/run/systemd/journal/syslog`. Use this option when you want to maintain plain rsyslog messages. Compared to `imjournal` the socket input currently offers more features, such as ruleset binding or filtering. To import **Journal** data through the socket, use the following configuration in `/etc/rsyslog.conf`:

```conf
module(load="imuxsock"
  SysSock.Use="on"
  SysSock.Name="/run/systemd/journal/syslog")
```

You can also output messages from **Rsyslog** to **Journal** with the `omjournal` module. Configure the output in `/etc/rsyslog.conf` as follows:

```conf
module(load="omjournal")
action(type="omjournal")
```

For instance, the following configuration forwards all received messages on tcp port 10514 to the **Journal**:

```conf
module(load="imtcp")
module(load="omjournal")

ruleset(name="remote") {
  action(type="omjournal")
}

input(type="imtcp" port="10514" ruleset="remote")
```

### 21.8. STRUCTURED LOGGING WITH RSYSLOG

On systems that produce large amounts of log data, it can be convenient to maintain log messages in a
structured format. With structured messages, it is easier to search for particular information, to produce statistics and to cope with changes and inconsistencies in message structure. Rsyslog uses the JSON (JavaScript Object Notation) format to provide structure for log messages.

Compare the following unstructured log message:

Oct 25 10:20:37 localhost anacron[1395]: Jobs will be executed sequentially

with a structured one:

{"timestamp":"2013-10-25T10:20:37", "host":"localhost", "program":"anacron", "pid":"1395", "msg":"Jobs will be executed sequentially"}

Searching structured data with use of key-value pairs is faster and more precise than searching text files with regular expressions. The structure also lets you to search for the same entry in messages produced by various applications. Also, JSON files can be stored in a document database such as MongoDB, which provides additional performance and analysis capabilities. On the other hand, a structured message requires more disk space than the unstructured one.

In rsyslog, log messages with meta data are pulled from Journal with use of the imjournal module. With the mmjsonparse module, you can parse data imported from Journal and from other sources and process them further, for example as a database output. For parsing to be successful, mmjsonparse requires input messages to be structured in a way that is defined by the Lumberjack project.

The Lumberjack project aims to add structured logging to rsyslog in a backward-compatible way. To identify a structured message, Lumberjack specifies the @cee: string that prepends the actual JSON structure. Also, Lumberjack defines the list of standard field names that should be used for entities in the JSON string. For more information on Lumberjack, see the section called “Online Documentation”.

The following is an example of a lumberjack-formatted message:

@cee: {"pid":17055, "uid":1000, "gid":1000, "appname":"logger", "msg":"Message text."}

To build this structure inside Rsyslog, a template is used, see Section 21.8.2, “Filtering Structured Messages”. Applications and servers can employ the libumberlog library to generate messages in the lumberjack-compliant form. For more information on libumberlog, see the section called “Online Documentation”.

21.8.1. Importing Data from Journal

The imjournal module is Rsyslog’s input module to natively read the journal files (see Section 21.7, “Interaction of Rsyslog and Journal”). Journal messages are then logged in text format as other rsyslog messages. However, with further processing, it is possible to translate meta data provided by Journal into a structured message.

To import data from Journal to Rsyslog, use the following configuration in /etc/rsyslog.conf:

module(load="imjournal"
       PersistStateInterval="number_of_messages"
With `number_of_messages`, you can specify how often the journal data must be saved. This will happen each time the specified number of messages is reached.

- Replace `path` with a path to the state file. This file tracks the journal entry that was the last one processed.

- With `seconds`, you set the length of the rate limit interval. The number of messages processed during this interval cannot exceed the value specified in `burst_number`. The default setting is 20,000 messages per 600 seconds. Rsyslog discards messages that come after the maximum burst within the time frame specified.

- With `IgnorePreviousMessages` you can ignore messages that are currently in Journal and import only new messages, which is used when there is no state file specified. The default setting is `off`. Please note that if this setting is off and there is no state file, all messages in the Journal are processed, even if they were already processed in a previous rsyslog session.

**NOTE**

You can use `imjournal` simultaneously with `imuxsock` module that is the traditional system log input. However, to avoid message duplication, you must prevent `imuxsock` from reading the Journal's system socket. To do so, use the `SysSock.Use` directive:

```plaintext
module(load="imjournal")
module(load="imuxsock")
  SysSock.Use="off"
  Socket="/run/systemd/journal/syslog")
```

You can translate all data and meta data stored by Journal into structured messages. Some of these meta data entries are listed in Example 21.19, “Verbose journalctl Output”, for a complete list of journal fields see the `systemd.journal-fields(7)` manual page. For example, it is possible to focus on `kernel journal fields`, that are used by messages originating in the kernel.

### 21.8.2. Filtering Structured Messages

To create a lumberjack-formatted message that is required by rsyslog's parsing module, use the following template:

```plaintext
template(name="CEETemplate" type="string" string="%TIMESTAMP% %HOSTNAME% %syslogtag% @cee: %$!all-json%\n")
```

This template prepends the `@cee:` string to the JSON string and can be applied, for example, when creating an output file with `omfile` module. To access JSON field names, use the `$!` prefix. For example, the following filter condition searches for messages with specific `hostname` and `UID`:

```plaintext
($!hostname == "hostname" && $!UID== "UID")
```
21.8.3. Parsing JSON

The mmjsonparse module is used for parsing structured messages. These messages can come from Journal or from other input sources, and must be formatted in a way defined by the Lumberjack project. These messages are identified by the presence of the @cee: string. Then, mmjsonparse checks if the JSON structure is valid and then the message is parsed.

To parse lumberjack-formatted JSON messages with mmjsonparse, use the following configuration in the /etc/rsyslog.conf:

```plaintext
module(load"mmjsonparse")
.* :mmjsonparse:
```

In this example, the mmjsonparse module is loaded on the first line, then all messages are forwarded to it. Currently, there are no configuration parameters available for mmjsonparse.

21.8.4. Storing Messages in the MongoDB

Rsyslog supports storing JSON logs in the MongoDB document database through the ommongodb output module.

To forward log messages into MongoDB, use the following syntax in the /etc/rsyslog.conf (configuration parameters for ommongodb are available only in the new configuration format; see Section 21.3, “Using the New Configuration Format”):

```plaintext
module(load"ommongodb")
.* action(type="ommongodb" server="DB_server" serverport="port" db="DB_name" collection="collection_name" uid="UID" pwd="password")
```

- Replace DB_server with the name or address of the MongoDB server. Specify port to select a non-standard port from the MongoDB server. The default port value is 0 and usually there is no need to change this parameter.

- With DB_name, you identify to which database on the MongoDB server you want to direct the output. Replace collection_name with the name of a collection in this database. In MongoDB, collection is a group of documents, the equivalent of an RDBMS table.

- You can set your login details by replacing UID and password.

You can shape the form of the final database output with use of templates. By default, rsyslog uses a template based on standard lumberjack field names.

21.9. DEBUGGING RSYSLOG

To run rsyslogd in debugging mode, use the following command:

```plaintext
rsyslogd -dn
```

With this command, rsyslogd produces debugging information and prints it to the standard output. The -n stands for “no fork”. You can modify debugging with environmental variables, for example, you can store the debug output in a log file. Before starting rsyslogd, type the following on the command line:
export RSYSLOG_DEBUGLOG="path"
export RSYSLOG_DEBUG="Debug"

Replace `path` with a desired location for the file where the debugging information will be logged. For a complete list of options available for the RSYSLOG_DEBUG variable, see the related section in the `rsyslogd(8)` manual page.

To check if syntax used in the `/etc/rsyslog.conf` file is valid use:

```bash
rsyslogd -N 1
```

Where 1 represents level of verbosity of the output message. This is a forward compatibility option because currently, only one level is provided. However, you must add this argument to run the validation.

## 21.10. USING THE JOURNAL

The Journal is a component of `systemd` that is responsible for viewing and management of log files. It can be used in parallel, or in place of a traditional syslog daemon, such as `rsyslogd`. The Journal was developed to address problems connected with traditional logging. It is closely integrated with the rest of the system, supports various logging technologies and access management for the log files.

Logging data is collected, stored, and processed by the Journal's `journald` service. It creates and maintains binary files called `journals` based on logging information that is received from the kernel, from user processes, from standard output, and standard error output of system services or via its native API. These journals are structured and indexed, which provides relatively fast seek times. Journal entries can carry a unique identifier. The `journald` service collects numerous meta data fields for each log message. The actual journal files are secured, and therefore cannot be manually edited.

### 21.10.1. Viewing Log Files

To access the journal logs, use the `journalctl` tool. For a basic view of the logs type as `root`:

```bash
journalctl
```

An output of this command is a list of all log files generated on the system including messages generated by system components and by users. The structure of this output is similar to one used in `/var/log/messages/` but with certain improvements:

- the priority of entries is marked visually. Lines of error priority and higher are highlighted with red color and a bold font is used for lines with notice and warning priority
- the time stamps are converted for the local time zone of your system
- all logged data is shown, including rotated logs
- the beginning of a boot is tagged with a special line

### Example 21.18. Example Output of journalctl

The following is an example output provided by the `journalctl` tool. When called without parameters, the listed entries begin with a time stamp, then the host name and application that performed the operation is mentioned followed by the actual message. This example shows the first three entries in the journal log:
In many cases, only the latest entries in the journal log are relevant. The simplest way to reduce `journalctl` output is to use the `-n` option that lists only the specified number of most recent log entries:

```bash
journalctl -n Number
```

Replace `Number` with the number of lines to be shown. When no number is specified, `journalctl` displays the ten most recent entries.

The `journalctl` command allows controlling the form of the output with the following syntax:

```bash
journalctl -o form
```

Replace `form` with a keyword specifying a desired form of output. There are several options, such as `verbose`, which returns full-structured entry items with all fields, `export`, which creates a binary stream suitable for backups and network transfer, and `json`, which formats entries as JSON data structures. For the full list of keywords, see the `journalctl(1)` manual page.

**Example 21.19. Verbose journalctl Output**

To view full meta data about all entries, type:

```bash
# journalctl -o verbose

Fri 2013-08-02 14:41:22 CEST
[s=e1021ca1b81e4fc688fad6a3ea21d35b;i=55c;b=78c81449c920439da57da7bd5c56a770;m=27cc
 _BOOT_ID=78c81449c920439da57da7bd5c56a770
PRIORITY=5
SYSLOG_FACILITY=3
_TRANSPORT=syslog
_MACHINE_ID=69d27b356a94476da859461d3a3bc6fd
_HOSTNAME=localhost.localdomain
_PID=562
_COMM=dbus-daemon
_EXE=/usr/bin/dbus-daemon
_CMLINE=/bin/dbus-daemon --system --address=systemd: --nofork
--nopidfile --systemd-activation
_SYSTEMD_CGROUP=/system/dbus.service
_SYSTEMD_UNIT=dbus.service
SYSLOG_IDENTIFIER=dbus
SYSLOG_PID=562
```
This example lists fields that identify a single log entry. These meta data can be used for message filtering as shown in the section called “Advanced Filtering”. For a complete description of all possible fields see the systemd.journal-fields(7) manual page.

21.10.2. Access Control

By default, Journal users without root privileges can only see log files generated by them. The system administrator can add selected users to the adm group, which grants them access to complete log files. To do so, type as root:

```
usermod -a -G adm username
```

Here, replace username with a name of the user to be added to the adm group. This user then receives the same output of the journalctl command as the root user. Note that access control only works when persistent storage is enabled for Journal.

21.10.3. Using The Live View

When called without parameters, journalctl shows the full list of entries, starting with the oldest entry collected. With the live view, you can supervise the log messages in real time as new entries are continuously printed as they appear. To start journalctl in live view mode, type:

```
journalctl -f
```

This command returns a list of the ten most current log lines. The journalctl utility then stays running and waits for new changes to show them immediately.

21.10.4. Filtering Messages

The output of the journalctl command executed without parameters is often extensive, therefore you can use various filtering methods to extract information to meet your needs.

Filtering by Priority

Log messages are often used to track erroneous behavior on the system. To view only entries with a selected or higher priority, use the following syntax:

```
journalctl -p priority
```

Here, replace priority with one of the following keywords (or with a number): debug (7), info (6), notice (5), warning (4), err (3), crit (2), alert (1), and emerg (0).

Example 21.20. Filtering by Priority
To view only entries with error or higher priority, use:

```
journalctl -p err
```

**Filtering by Time**

To view log entries only from the current boot, type:

```
journalctl -b
```

If you reboot your system just occasionally, the `-b` will not significantly reduce the output of `journalctl`. In such cases, time-based filtering is more helpful:

```
journalctl --since=value --until=value
```

With `--since` and `--until`, you can view only log messages created within a specified time range. You can pass values to these options in form of date or time or both as shown in the following example.

**Example 21.21. Filtering by Time and Priority**

Filtering options can be combined to reduce the set of results according to specific requests. For example, to view the `warning` or higher priority messages from a certain point in time, type:

```
journalctl -p warning --since="2013-3-16 23:59:59"
```

**Advanced Filtering**

Example 21.19, “Verbose journalctl Output” lists a set of fields that specify a log entry and can all be used for filtering. For a complete description of meta data that `systemd` can store, see the `systemd.journal-fields(7)` manual page. This meta data is collected for each log message, without user intervention. Values are usually text-based, but can take binary and large values; fields can have multiple values assigned though it is not very common.

To view a list of unique values that occur in a specified field, use the following syntax:

```
journalctl -F fieldname
```

Replace `fieldname` with a name of a field you are interested in.

To show only log entries that fit a specific condition, use the following syntax:

```
journalctl fieldname=value
```

Replace `fieldname` with a name of a field and `value` with a specific value contained in that field. As a result, only lines that match this condition are returned.
As the number of meta data fields stored by systemd is quite large, it is easy to forget the exact name of the field of interest. When unsure, type:

```
journalctl
```

and press the Tab key two times. This shows a list of available field names. Tab completion based on context works on field names, so you can type a distinctive set of letters from a field name and then press Tab to complete the name automatically. Similarly, you can list unique values from a field. Type:

```
journalctl fieldname=
```

and press Tab two times. This serves as an alternative to `journalctl -F fieldname`.

You can specify multiple values for one field:

```
journalctl fieldname=value1 fieldname=value2 ...
```

Specifying two matches for the same field results in a logical OR combination of the matches. Entries matching `value1` or `value2` are displayed.

Also, you can specify multiple field-value pairs to further reduce the output set:

```
journalctl fieldname1=value fieldname2=value ...
```

If two matches for different field names are specified, they will be combined with a logical AND. Entries have to match both conditions to be shown.

With use of the `+` symbol, you can set a logical OR combination of matches for multiple fields:

```
journalctl fieldname1=value + fieldname2=value ...
```

This command returns entries that match at least one of the conditions, not only those that match both of them.

**Example 21.22. Advanced filtering**

To display entries created by `avahi-daemon.service` or `crond.service` under user with UID 70, use the following command:

```
journalctl _UID=70 _SYSTEMD_UNIT=avahi-daemon.service _SYSTEMD_UNIT=crond.service
```

Since there are two values set for the `_SYSTEMD_UNIT` field, both results will be displayed, but only when matching the `_UID=70` condition. This can be expressed simply as: (UID=70 and (avahi or cron)).

You can apply the aforementioned filtering also in the live-view mode to keep track of the latest changes in the selected group of log entries:
journalctl -f fieldname=value ...

21.10.5. Enabling Persistent Storage

By default, Journal stores log files only in memory or a small ring-buffer in the /run/log/journal/ directory. This is sufficient to show recent log history with journalctl. This directory is volatile, log data is not saved permanently. With the default configuration, syslog reads the journal logs and stores them in the /var/log/ directory. With persistent logging enabled, journal files are stored in /var/log/journal which means they persist after reboot. Journal can then replace rsyslog for some users (but see the chapter introduction).

Enabled persistent storage has the following advantages

- Richer data is recorded for troubleshooting in a longer period of time
- For immediate troubleshooting, richer data is available after a reboot
- Server console currently reads data from journal, not log files

Persistent storage has also certain disadvantages:

- Even with persistent storage the amount of data stored depends on free memory, there is no guarantee to cover a specific time span
- More disk space is needed for logs

To enable persistent storage for Journal, create the journal directory manually as shown in the following example. As root type:

```bash
mkdir -p /var/log/journal/
```

Then, restart journald to apply the change:

```bash
systemctl restart systemd-journald
```

21.11. MANAGING LOG FILES IN A GRAPHICAL ENVIRONMENT

As an alternative to the aforementioned command-line utilities, Red Hat Enterprise Linux 7 provides an accessible GUI for managing log messages.

21.11.1. Viewing Log Files

Most log files are stored in plain text format. You can view them with any text editor such as Vi or Emacs. Some log files are readable by all users on the system; however, root privileges are required to read most log files.

To view system log files in an interactive, real-time application, use the System Log.
NOTE

In order to use the System Log, first ensure the gnome-system-log package is installed on your system by running, as root:

```
-]# yum install gnome-system-log
```

For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

After you have installed the gnome-system-log package, open the System Log by clicking Applications → System Tools → System Log, or type the following command at a shell prompt:

```
-]$ gnome-system-log
```

The application only displays log files that exist; thus, the list might differ from the one shown in Figure 21.2, “System Log”.

<table>
<thead>
<tr>
<th>boot.log</th>
<th>cron updated today 04:23:55 PM</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>cron</strong></td>
<td>Oct 6 12:44:02 localhost run-parts(/etc/cron.daily)</td>

<td>Oct 6 13:24:02 localhost anacron[4239]: Job `cron.monthly'</td>
</tr>
<tr>
<td></td>
<td>Oct 6 13:27:51 localhost crond[5886]: (CRON) INFO (F</td>
</tr>
</tbody>
</table>

Figure 21.2. System Log

The System Log application lets you filter any existing log file. Click on the button marked with the gear symbol to view the menu, select Filters → Manage Filters to define or edit the desired filter.
Adding or editing a filter lets you define its parameters as is shown in Figure 21.4, “System Log - defining a filter”.

When defining a filter, the following parameters can be edited:

- **Name** — Specifies the name of the filter.
- **Regular Expression** — Specifies the regular expression that will be applied to the log file and will attempt to match any possible strings of text in it.
- **Effect**
  - **Highlight** — If checked, the found results will be highlighted with the selected color. You may select whether to highlight the background or the foreground of the text.
  - **Hide** — If checked, the found results will be hidden from the log file you are viewing.
When you have at least one filter defined, it can be selected from the Filters menu and it will automatically search for the strings you have defined in the filter and highlight or hide every successful match in the log file you are currently viewing.

When you select the Show matches only option, only the matched strings will be shown in the log file you are currently viewing.

21.11.2. Adding a Log File

To add a log file you want to view in the list, select File → Open. This will display the Open Log window where you can select the directory and file name of the log file you want to view. Figure 21.6, “System Log - adding a log file” illustrates the Open Log window.
Click on the Open button to open the file. The file is immediately added to the viewing list where you can select it and view its contents.

**NOTE**

The System Log also allows you to open log files zipped in the .gz format.

### 21.11.3. Monitoring Log Files

System Log monitors all opened logs by default. If a new line is added to a monitored log file, the log name appears in bold in the log list. If the log file is selected or displayed, the new lines appear in bold at the bottom of the log file. Figure 21.7, “System Log - new log alert” illustrates a new alert in the cron log file and in the messages log file. Clicking on the messages log file displays the logs in the file with the new lines in bold.
Figure 21.7. System Log - new log alert

21.12. ADDITIONAL RESOURCES

For more information on how to configure the `rsyslog` daemon and how to locate, view, and monitor log files, see the resources listed below.

**Installed Documentation**

- `rsyslogd`(8) – The manual page for the `rsyslogd` daemon documents its usage.
- `rsyslog.conf`(5) – The manual page named `rsyslog.conf` documents available configuration options.
- `logrotate`(8) – The manual page for the `logrotate` utility explains in greater detail how to configure and use it.
- `journalctl`(1) – The manual page for the `journalctl` daemon documents its usage.
- `journald.conf`(5) – This manual page documents available configuration options.
- `systemd.journal-fields`(7) – This manual page lists special Journal fields.

**Installable Documentation**

`/usr/share/doc/rsyslog/version/html/index.html` – This file, which is provided by the `rsyslog-doc` package from the Optional channel, contains information on `rsyslog`. See Section 8.5.7, “Adding the Optional and Supplementary Repositories” for more information on Red Hat additional channels. Before accessing the documentation, you must run the following command as `root`:

```
~]# yum install rsyslog-doc
```
Online Documentation
The rsyslog home page offers additional documentation, configuration examples, and video tutorials. Make sure to consult the documents relevant to the version you are using:

- *RainerScript documentation on the rsyslog Home Page* — Commented summary of data types, expressions, and functions available in RainerScript.

- *rsyslog version 7 documentation on the rsyslog home page* — Version 7 of rsyslog is available for Red Hat Enterprise Linux 7 in the rsyslog package.

- *Description of queues on the rsyslog Home Page* — General information on various types of message queues and their usage.

See Also

- *Chapter 5, Gaining Privileges* documents how to gain administrative privileges by using the `su` and `sudo` commands.

- *Chapter 9, Managing Services with systemd* provides more information on systemd and documents how to use the `systemctl` command to manage system services.
CHAPTER 22. AUTOMATING SYSTEM TASKS

You can configure Red Hat Enterprise Linux to automatically run tasks, also known as jobs:

- regularly at specified time using cron, see Section 22.1, “Scheduling a Recurring Job Using Cron”
- asynchronously at certain days using anacron, see Section 22.2, “Scheduling a Recurring Asynchronous Job Using Anacron”
- once at a specific time using at, see Section 22.3, “Scheduling a Job to Run at a Specific Time Using at”
- once when system load average drops to a specified value using batch, see Section 22.4, “Scheduling a Job to Run on System Load Drop Using batch”
- once on the next boot, see Section 22.5, “Scheduling a Job to Run on Next Boot Using a systemd Unit File”

This chapter describes how to perform these tasks.

22.1. SCHEDULING A RECURRING JOB USING CRON

Cron is a service that enables you to schedule running a task, often called a job, at regular times. A cron job is only executed if the system is running on the scheduled time. For scheduling jobs that can postpone their execution to when the system boots up, so a job is not "lost" if the system is not running, see Section 22.3, “Scheduling a Job to Run at a Specific Time Using at”.

Users specify cron jobs in cron table files, also called crontab files. These files are then read by the crond service, which executes the jobs.

22.1.1. Prerequisites for Cron Jobs

Before scheduling a cron job:

1. Install the cronie package:

   ```
   ~]# yum install cronie
   ```

2. The crond service is enabled - made to start automatically at boot time - upon installation. If you disabled the service, enable it:

   ```
   ~]# systemctl enable crond.service
   ```

3. Start the crond service for the current session:

   ```
   ~]# systemctl start crond.service
   ```

4. *(optional)* Configure cron. For example, you can change:

   - shell to be used when executing jobs
   - the PATH environment variable
mail addressee if a job sends emails.

See the crontab(5) manual page for information on configuring cron.

22.1.2. Scheduling a Cron Job

Scheduling a Job as root User

The root user uses the cron table in /etc/crontab, or, preferably, creates a cron table file in /etc/cron.d/. Use this procedure to schedule a job as root:

1. Choose:
   - in which minutes of an hour to execute the job. For example, use 0, 10, 20, 30, 40, 50 or 0/10 to specify every 10 minutes of an hour.
   - in which hours of a day to execute the job. For example, use 17-20 to specify time from 17:00 to 20:59.
   - in which days of a month to execute the job. For example, use 15 to specify 15th day of a month.
   - in which months of a year to execute the job. For example, use Jun, Jul, Aug or 6, 7, 8 to specify the summer months of the year.
   - in which days of the week to execute the job. For example, use * for the job to execute independently of the day of week.

Combine the chosen values into the time specification. The above example values result into this specification:

   0, 10, 20, 30, 40, 50 17-20 15 Jun, Jul, Aug *

2. Specify the user. The job will execute as if run by this user. For example, use root.

3. Specify the command to execute. For example, use /usr/local/bin/my-script.sh

4. Put the above specifications into a single line:

   0,10,20,30,40,50 17-20 15 Jun, Jul, Aug * root /usr/local/bin/my-script.sh

5. Add the resulting line to /etc/crontab, or, preferably, create a cron table file in /etc/cron.d/ and add the line there.

The job will now run as scheduled.

For full reference on how to specify a job, see the crontab(5) manual page. For basic information, see the beginning of the /etc/crontab file:

SHELL=/bin/bash
PATH=/sbin:/bin:/usr/sbin:/usr/bin
MAILTO=root

# For details see man 4 crontabs
# Example of job definition:
# .---------------- minute (0 - 59)
# |  .------------- hour (0 - 23)
# |  |  .---------- day of month (1 - 31)
# |  |  |  .------- month (1 - 12) OR jan,feb,mar,apr ...
# |  |  |  |  .---- day of week (0 - 6) (Sunday=0 or 7) OR
# sun,mon,tue,wed,thu,fri,sat
# |  |  |  |  |
# *  *  *  *  * user-name  command to be executed

Scheduling a Job as Non-root User
Non-root users can use the `crontab` utility to configure cron jobs. The jobs will run as if executed by that user.

To create a cron job as a specific user:

1. From the user's shell, run:
   ```
   [bob@localhost ~]$ crontab -e
   ```
   This will start editing of the user's own crontab file using the editor specified by the `VISUAL` or `EDITOR` environment variable.

2. Specify the job in the same way as in Scheduling a cron Job as root user, but leave out the field with user name. For example, instead of adding
   ```
   0,10,20,30,40,50 17-20 15 Jun,Jul,Aug * bob /home/bob/bin/script.sh
   ```
   add:
   ```
   0,10,20,30,40,50 17-20 15 Jun,Jul,Aug * /home/bob/bin/script.sh
   ```

3. Save the file and exit the editor.

4. (optional) To verify the new job, list the contents of the current user's crontab file by running:
   ```
   [bob@localhost ~]$ crontab -l
   @daily /home/bob/bin/script.sh
   ```

Scheduling Hourly, Daily, Weekly, and Monthly Jobs
To schedule an hourly, daily, weekly, or monthly job:

1. Put the actions you want your job to execute into a shell script.

2. Put the shell script into one of the following directories:
   - `/etc/cron.hourly/`
   - `/etc/cron.daily/`
   - `/etc/cron.weekly/`
   - `/etc/cron.monthly/`
From now, your script will be executed - the crond service automatically executes any scripts present in `/etc/cron.hourly`, `/etc/cron.daily`, `/etc/cron.weekly`, and `/etc/cron.monthly` directories at their corresponding times.

### 22.2. SCHEDULING A RECURRING ASYNCHRONOUS JOB USING ANACRON

Anacron, like cron, is a service that enables you to schedule running a task, often called a job, at regular times. However, anacron differs from cron in two ways:

- If the system is not running at the scheduled time, an anacron job is postponed until the system is running;
- An anacron job can run once per day at most.

Users specify anacron jobs in anacron table files, also called anacrontab files. These files are then read by the crond service, which executes the jobs.

#### 22.2.1. Prerequisites for Anacron Jobs

Before scheduling an anacron job:

1. Verify that you have the cronie-anacron package installed:

   ```bash
   ~]# rpm -q cronie-anacron
   ```

   The cronie-anacron is likely to be installed already, because it is a sub-package of the cronie package. If it is not installed, use this command:

   ```bash
   ~]# yum install cronie-anacron
   ```

2. The crond service is enabled - made to start automatically at boot time - upon installation. If you disabled the service, enable it:

   ```bash
   ~]# systemctl enable crond.service
   ```

3. Start the crond service for the current session:

   ```bash
   ~]# systemctl start crond.service
   ```

4. (optional) Configure anacron. For example, you can change:
   - shell to be used when executing jobs
   - the PATH environment variable
   - mail addressee if a job sends emails.

   See the anacrontab(5) manual page for information on configuring anacron.

#### 22.2.2. Scheduling an Anacron Job
**Scheduling an anacron Job as root User**
The root user uses the anacron table in /etc/anacrontab. Use the following procedure to schedule a job as root.

**Procedure 22.1. Scheduling an anacron Job as root User**

1. Choose:
   - Frequency of executing the job. For example, use 1 to specify every day or 3 to specify once in 3 days.
   - The delay of executing the job. For example, use 0 to specify no delay or 60 to specify 1 hour of delay.
   - The job identifier, which will be used for logging. For example, use my.anacron.job to log the job with the my.anacron.job string.
   - The command to execute. For example, use /usr/local/bin/my-script.sh

Combine the chosen values into the job specification. Here is an example specification:

```
3 60 cron.daily /usr/local/bin/my-script.sh
```

2. Add the resulting line to /etc/anacrontab.

The job will now run as scheduled.

For simple job examples, see the /etc/anacrontab file. For full reference on how to specify a job, see the anacrontab(5) manual page.

**Scheduling Hourly, Daily, Weekly, and Monthly Jobs**
You can schedule daily, weekly, and monthly jobs with anacron. See the section called “Scheduling Hourly, Daily, Weekly, and Monthly Jobs”.

**22.3. SCHEDULING A JOB TO RUN AT A SPECIFIC TIME USING AT**

To schedule a one-time task, also called a job, to run once at a specific time, use the at utility.

Users specify at jobs using the at utility. The jobs are then executed by the atd service.

**22.3.1. Prerequisites for At Jobs**

Before scheduling an at job:

1. Install the at package:

```
~]# yum install at
```

2. The atd service is enabled - made to start automatically at boot time - upon installation. If you disabled the service, enable it:

```
~]# systemctl enable atd.service
```
3. Start the `atd` service for the current session:

```
~]# systemctl start atd.service
```

### 22.3.2. Scheduling an At Job

1. A job is always run by some user. Log in as the desired user and run:

```
~]# at time
```

Replace `time` with the time specification.

For details on specifying time, see the `at(1)` manual page and the `/usr/share/doc/at/timespec` file.

**Example 22.1. Specifying Time for At**

To execute the job at 15:00, run:

```
~]# at 15:00
```

If the specified time has passed, the job is executed at the same time the next day.

To execute the job on August 20 2017, run:

```
~]# at August 20 2017
```

or

```
~]# at 082017
```

To execute the job 5 days from now, run:

```
~]# now + 5 days
```

2. At the displayed `at>` prompt, enter the command to execute and press Enter:

```
~]# at 15:00
at> sh /usr/local/bin/my-script.sh
at>
```

Repeat this step for every command you want to execute.
NOTE

The at> prompt shows which shell it will use:

```
warning: commands will be executed using /bin/sh
```

The at utility uses the shell set in user’s SHELL environment variable, or the user’s login shell, or /bin/sh, whichever is found first.

3. Press Ctrl+D on an empty line to finish specifying the job.

NOTE

If the set of commands or the script tries to display information to standard output, the output is emailed to the user.

Viewing Pending Jobs
To view the list of pending jobs, use the `atq` command:

```
~]# atq
26 Thu Feb 23 15:00:00 2017 a root
28 Thu Feb 24 17:30:00 2017 a root
```

Each job is listed on a separate line in the following format:

```
job_number scheduled_date scheduled_hour job_class user_name
```

The job_queue column specifies whether a job is an at or a batch job. a stands for at, b stands for batch.

Non-root users only see their own jobs. The root user sees jobs for all users.

Deleting a Scheduled Job
To delete a scheduled job:

1. List pending jobs with the `atq` command:

```
~]# atq
26 Thu Feb 23 15:00:00 2017 a root
28 Thu Feb 24 17:30:00 2017 a root
```

2. Find the job you want to delete by its scheduled time and the user.

3. Run the `atrm` command, specifying the job by its number:

```
~]# atrm 26
```

22.3.2.1. Controlling Access to At and Batch

You can restrict access to the at and batch commands for specific users. To do this, put user names into `/etc/at.allow` or `/etc/at.deny` according to these rules:
Both access control files use the same format: one user name on each line.

No white space is permitted in either file.

If the `at.allow` file exists, only users listed in the file are allowed to use `at` or `batch`, and the `at.deny` file is ignored.

If `at.allow` does not exist, users listed in `at.deny` are not allowed to use `at` or `batch`.

The root user is not affected by the access control files and can always execute the `at` and `batch` commands.

The `at` daemon (atd) does not have to be restarted if the access control files are modified. The access control files are read each time a user tries to execute the `at` or `batch` commands.

**22.4. SCHEDULING A JOB TO RUN ON SYSTEM LOAD DROP USING BATCH**

To schedule a one-time task, also called a job, to run when the system load average drops below the specified value, use the `batch` utility. This can be useful for performing resource-demanding tasks or for preventing the system from being idle.

Users specify `batch` jobs using the `batch` utility. The jobs are then executed by the atd service.

**22.4.1. Prerequisites for Batch Jobs**

The `batch` utility is provided in the `at` package, and `batch` jobs are managed by the `atd` service. Hence, the prerequisites for `batch` jobs are the same as for `at` jobs. See Section 22.3.1, “Prerequisites for At Jobs”.

**22.4.2. Scheduling a Batch Job**

1. A job is always run by some user. Log in as the desired user and run:

   ```shell
   ~# batch
   ```

2. At the displayed `at>` prompt, enter the command to execute and press Enter:

   ```shell
   ~# batch
   at> sh /usr/local/bin/my-script.sh
   ```

   Repeat this step for every command you want to execute.

   **NOTE**

   The `at>` prompt shows which shell it will use:

   ```shell
   warning: commands will be executed using /bin/sh
   ```

   The `batch` utility uses the shell set in user’s SHELL environment variable, or the user's login shell, or `/bin/sh`, whichever is found first.
3. Press Ctrl+D on an empty line to finish specifying the job.

NOTE

If the set of commands or the script tries to display information to standard output, the output is emailed to the user.

Changing the Default System Load Average Limit
By default, batch jobs start when system load average drops below 0.8. This setting is kept in the `atq` service. To change the system load limit:

1. To the `/etc/sysconfig/atd` file, add this line:
   
   ```
   OPTS='-l x'
   ```

   Substitute `x` with the new load average. For example:

   ```
   OPTS='-l 0.5'
   ```

2. Restart the `atq` service:

   ```
   # systemctl restart atq
   ```

Viewing Pending Jobs
To view the list of pending jobs, use the `atq` command. See the section called “Viewing Pending Jobs”.

Deleting a Scheduled Job
To delete a scheduled job, use the `atrm` command. See the section called “Deleting a Scheduled Job”.

Controlling Access to Batch
You can also restrict the usage of the `batch` utility. This is done for the `batch` and `at` utilities together. See Section 22.3.2.1, “Controlling Access to At and Batch”.

22.5. SCHEDULING A JOB TO RUN ON NEXT BOOT USING A SYSTEMD UNIT FILE

The cron, anacron, at, and batch utilities allow scheduling jobs for specific times or for when system workload reaches a certain level. It is also possible to create a job that will run during the next system boot. This is done by creating a systemd unit file that specifies the script to run and its dependencies.

To configure a script to run on the next boot:

1. Create the systemd unit file that specifies at which stage of the boot process to run the script. This example shows a unit file with a reasonable set of `Wants=` and `After=` dependencies:

   ```
   ~]# cat /etc/systemd/system/one-time.service
   [Unit]
   # The script needs to execute after:
   # network interfaces are configured
   Wants=network-online.target
   After=network-online.target
   # all remote filesystems (NFS/_netdev) are mounted
   ```
After=remote-fs.target
# name (DNS) and user resolution from remote databases (AD/LDAP) are available
After=nss-user-lookup.target nss-lookup.target
# the system clock has synchronized
After=time-sync.target

[Service]
Type=oneshot
ExecStart=/usr/local/bin/foobar.sh

[Install]
WantedBy=multi-user.target

If you use this example:

- substitute /usr/local/bin/foobar.sh with the name of your script
- modify the set of After= entries if necessary

For information on specifying the stage of boot, see Section 9.6, “Creating and Modifying systemd Unit Files”.

2. If you want the systemd service to stay active after executing the script, add the RemainAfterExit=yes line to the [Service] section:

   [Service]
   Type=oneshot
   RemainAfterExit=yes
   ExecStart=/usr/local/bin/foobar.sh

3. Reload the systemd daemon:

   ~]# systemctl daemon-reload

4. Enable the systemd service:

   ~]# systemctl enable one-time.service

5. Create the script to execute:

   ~]# cat /usr/local/bin/foobar.sh
   #!/bin/bash
   touch /root/test_file

6. If you want the script to run during the next boot only, and not on every boot, add a line that disables the systemd unit:

   #!/bin/bash
   touch /root/test_file
   systemctl disable one-time.service
7. Make the script executable:

```bash
~]$ chmod +x /usr/local/bin/foobar.sh
```

## 22.6. ADDITIONAL RESOURCES

For more information on automating system tasks on Red Hat Enterprise Linux, see the resources listed below.

### Installed Documentation

- **cron** - The manual page for the `cron` daemon documents how `cron` works and how to change its behavior.

- **crontab** - The manual page for the `crontab` utility provides a complete list of supported options.

- **crontab(5)** - This section of the manual page for the `crontab` utility documents the format of `crontab` files.
CHAPTER 23. AUTOMATIC BUG REPORTING TOOL (ABRT)

23.1. INTRODUCTION TO ABRT

The Automatic Bug Reporting Tool, commonly abbreviated as ABRT, is a set of tools that is designed to help users detect and report application crashes. Its main purpose is to ease the process of reporting issues and finding solutions. In this context, the solution can be a Bugzilla ticket, a knowledge-base article, or a suggestion to update a package to a version containing a fix.

ABRT consists of the abrtd daemon and a number of system services and utilities for processing, analyzing, and reporting detected problems. The daemon runs silently in the background most of the time and springs into action when an application crashes or a kernel oops is detected. The daemon then collects the relevant problem data, such as a core file if there is one, the crashing application's command line parameters, and other data of forensic utility.

ABRT currently supports the detection of crashes in applications written in the C, C++, Java, Python, and Ruby programming languages, as well as X.Org crashes, kernel oopses, and kernel panics. See Section 23.4, “Detecting Software Problems” for more detailed information on the types of failures and crashes supported, and the way the various types of crashes are detected.

The identified problems can be reported to a remote issue tracker, and the reporting can be configured to happen automatically whenever an issue is detected. Problem data can also be stored locally or on a dedicated system and reviewed, reported, and deleted manually by the user. The reporting tools can send problem data to a Bugzilla database or the Red Hat Technical Support (RHTSupport) website. The tools can also upload it using FTP or SCP, send it as an email, or write it to a file.

The ABRT component that handles existing problem data (as opposed to, for example, the creation of new problem data) is a part of a separate project, libreport. The libreport library provides a generic mechanism for analyzing and reporting problems, and it is used by applications other than ABRT as well. However, ABRT and libreport operation and configuration are closely integrated. They are, therefore, discussed as one in this document.

23.2. INSTALLING ABRT AND STARTING ITS SERVICES

In order to use ABRT, ensure that the abrt-desktop or the abrt-cli package is installed on your system. The abrt-desktop package provides a graphical user interface for ABRT, and the abrt-cli package contains a tool for using ABRT on the command line. You can also install both. The general workflow with both the ABRT GUI and the command line tool is procedurally similar and follows the same pattern.

WARNING

Please note that installing the ABRT packages overwrites the /proc/sys/kernel/core_pattern file, which can contain a template used to name core-dump files. The content of this file will be overwritten to:

```
|/usr/libexec/abrt-hook-ccpp %s %c %p %u %g %t e
```
See Section 8.2.4, “Installing Packages” for general information on how to install packages using the Yum package manager.

23.2.1. Installing the ABRT GUI

The ABRT graphical user interface provides an easy-to-use front end for working in a desktop environment. You can install the required package by running the following command as the root user:

```
~]# yum install abrt-desktop
```

Upon installation, the ABRT notification applet is configured to start automatically when your graphical desktop session starts. You can verify that the ABRT applet is running by issuing the following command in a terminal:

```
~]$ ps -el | grep abrt-applet
0 S 500 2036 1824 0 80 0 - 61604 poll_s ? 00:00:00 abrt-applet
```

If the applet is not running, you can start it manually in your current desktop session by running the `abrt-applet` program:

```
~]$ abrt-applet &
[1] 2261
```

23.2.2. Installing ABRT for the Command Line

The command line interface is useful on headless machines, remote systems connected over a network, or in scripts. You can install the required package by running the following command as the root user:

```
~]# yum install abrt-cli
```

23.2.3. Installing Supplementary ABRT Tools

To receive email notifications about crashes detected by ABRT, you need to have the `libreport-plugin-mailx` package installed. You can install it by executing the following command as root:

```
~]# yum install libreport-plugin-mailx
```

By default, it sends notifications to the root user at the local machine. The email destination can be configured in the `/etc/libreport/plugins/mailx.conf` file.

To have notifications displayed in your console at login time, install the `abrt-console-notification` package as well.

ABRT can detect, analyze, and report various types of software failures. By default, ABRT is installed with support for the most common types of failures, such as crashes of C and C++ applications. Support for other types of failures is provided by independent packages. For example, to install support for detecting exceptions in applications written using the Java language, run the following command as root:

```
~]# yum install abrt-java-connector
```
See Section 23.4, “Detecting Software Problems” for a list of languages and software projects which ABRT supports. The section also includes a list of all corresponding packages that enable the detection of the various types of failures.

23.2.4. Starting the ABRT Services

The abrd daemon requires the abrt user to exist for file system operations in the /var/spool/abrt directory. When the abrt package is installed, it automatically creates the abrt user whose UID and GID is 173, if such user does not already exist. Otherwise, the abrt user can be created manually. In that case, any UID and GID can be chosen, because abrd does not require a specific UID and GID.

The abrd daemon is configured to start at boot time. You can use the following command to verify its current status:

```bash
~]$ systemctl is-active abrd.service
active
```

If systemctl returns inactive or unknown, the daemon is not running. You can start it for the current session by entering the following command as root:

```bash
~]$ systemctl start abrd.service
```

You can use the same commands to start or check status of related error-detection services. For example, make sure the abrt-ccpp service is running if you want ABRT to detect C or C++ crashes. See Section 23.4, “Detecting Software Problems” for a list of all available ABRT detection services and their respective packages.

With the exception of the abrt-vmcore and abrt-pstoreoops services, which are only started when a kernel panic or kernel oops occurs, all ABRT services are automatically enabled and started at boot time when their respective packages are installed. You can disable or enable any ABRT service by using the systemctl utility as described in Chapter 9, Managing Services with systemd.

23.2.5. Testing ABRT Crash Detection

To test that ABRT works properly, use the kill command to send the SEGV signal to terminate a process. For example, start a sleep process and terminate it with the kill command in the following way:

```bash
~]$ sleep 100 &
[1] 2823
~]$ kill -s SEGV 2823
```

ABRT detects a crash shortly after executing the kill command, and, provided a graphical session is running, the user is notified of the detected problem by the GUI notification applet. On the command line, you can check that the crash was detected by running the abrt-cli list command or by examining the crash dump created in the /var/tmp/abrt/ directory. See Section 23.5, “Handling Detected Problems” for more information on how to work with detected crashes.

23.3. CONFIGURING ABRT

A problem life cycle is driven by events in ABRT. For example:
• Event #1 — a problem-data directory is created.

• Event #2 — problem data is analyzed.

• Event #3 — the problem is reported to Bugzilla.

Whenever a problem is detected, ABRT compares it with all existing problem data and determines whether that same problem has already been recorded. If it has, the existing problem data is updated, and the most recent (duplicate) problem is not recorded again. If the problem is not recognized by ABRT, a problem-data directory is created. A problem-data directory typically consists of files such as: analyzer, architecture, coredump, cmdline, executable, kernel, os_release, reason, time, and uid.

Other files, such as backtrace, can be created during the analysis of the problem, depending on which analyzer method is used and its configuration settings. Each of these files holds specific information about the system and the problem itself. For example, the kernel file records the version of a crashed kernel.

After the problem-data directory is created and problem data gathered, you can process the problem using either the ABRT GUI, or the abrt-cli utility for the command line. See Section 23.5, “Handling Detected Problems” for more information about the ABRT tools provided for working with recorded problems.

23.3.1. Configuring Events

ABRT events use plugins to carry out the actual reporting operations. Plugins are compact utilities that the events call to process the content of problem-data directories. Using plugins, ABRT is capable of reporting problems to various destinations, and almost every reporting destination requires some configuration. For instance, Bugzilla requires a user name, password, and a URL pointing to an instance of the Bugzilla service.

Some configuration details can have default values (such as a Bugzilla URL), but others cannot have sensible defaults (for example, a user name). ABRT looks for these settings in configuration files, such as report_Bugzilla.conf, in the /etc/libreport/events/ or $HOME/.cache/abrt/events/ directories for system-wide or user-specific settings respectively. The configuration files contain pairs of directives and values.

These files are the bare minimum necessary for running events and processing the problem-data directories. The gnome-abrt and abrt-cli tools read the configuration data from these files and pass it to the events they run.

Additional information about events (such as their description, names, types of parameters that can be passed to them as environment variables, and other properties) is stored in event_name.xml files in the /usr/share/libreport/events/ directory. These files are used by both gnome-abrt and abrt-cli to make the user interface more friendly. Do not edit these files unless you want to modify the standard installation. If you intend to do that, copy the file to be modified to the /etc/libreport/events/ directory and modify the new file. These files can contain the following information:

• a user-friendly event name and description (Bugzilla, Report to Bugzilla bug tracker),

• a list of items in a problem-data directory that are required for the event to succeed,

• a default and mandatory selection of items to send or not send,

• whether the GUI should prompt for data review,
what configuration options exist, their types (string, Boolean, etc.), default value, prompt string, etc.; this lets the GUI build appropriate configuration dialogs.

For example, the report(Logger event accepts an output filename as a parameter. Using the respective event.name.xml file, the ABRT GUI determines which parameters can be specified for a selected event and allows the user to set the values for these parameters. The values are saved by the ABRT GUI and reused on subsequent invocations of these events. Note that the ABRT GUI saves configuration options using the GNOME Keyring tool and by passing them to events, it overrides data from text configuration files.

To open the graphical Configuration window, choose Automatic Bug Reporting Tool → Preferences from within a running instance of the gnome-abrt application. This window shows a list of events that can be selected during the reporting process when using the GUI. When you select one of the configurable events, you can click the Configure button and modify the settings for that event.

Figure 23.1. Configuring ABRT Events
IMPORTANT

All files in the `/etc/libreport/` directory hierarchy are world-readable and are meant to be used as global settings. Thus, it is not advisable to store user names, passwords, or any other sensitive data in them. The per-user settings (set in the GUI application and readable by the owner of `$HOME`) are safely stored in `GNOME Keyring`, or they can be stored in a text configuration file in `$HOME/.abrt/` for use with `abrt-cli`.

The following table shows a selection of the default analyzing, collecting, and reporting events provided by the standard installation of ABRT. The table lists each event's name, identifier, configuration file from the `/etc/libreport/events.d/` directory, and a brief description. Note that while the configuration files use the event identifiers, the ABRT GUI refers to the individual events using their names. Note also that not all of the events can be set up using the GUI. For information on how to define a custom event, see Section 23.3.2, “Creating Custom Events”.

Table 23.1. Standard ABRT Events

<table>
<thead>
<tr>

<td>Runs GDB (the GNU debugger) on the problem data of an application and generates a backtrace of the program.</td>
</tr>
</tbody>
</table>
### 23.3.2. Creating Custom Events

Each event is defined by one rule structure in a respective configuration file. The configuration files are typically stored in the `/etc/libreport/events.d/` directory. These configuration files are loaded by the main configuration file, `/etc/libreport/report_event.conf`. There is no need to edit the default configuration files because abrt will run the scripts contained in `/etc/libreport/events.d/`. This file accepts shell metacharacters (`*`, `$`, `?`, etc.) and interprets relative paths relatively to its location.

Each rule starts with a line with a non-space leading character, and all subsequent lines starting with the space character or the tab character are considered a part of this rule. Each rule consists of two parts, a condition part and a program part. The condition part contains conditions in one of the following forms:

- `VAR=VAL`
- `VAR!=VAL`
- `VAL~=REGEX`

where:

- `VAR` is either the `EVENT` keyword or a name of a problem-data directory element (such as executable, package, hostname, etc.),
- `VAL` is either a name of an event or a problem-data element, and
- `REGEX` is a regular expression.

The program part consists of program names and shell-interpretable code. If all conditions in the condition part are valid, the program part is run in the shell. The following is an event example:

```bash
EVENT=post-create date > /tmp/dt
echo $HOSTNAME `uname -r`
```

This event would overwrite the contents of the `/tmp/dt` file with the current date and time and print the host name of the machine and its kernel version on the standard output.

Here is an example of a more complex event, which is actually one of the predefined events. It saves relevant lines from the `~/.xsession-errors` file to the problem report of any problem for which the

<table>
<thead>
<tr>
<th>Name</th>
<th>Identifier and Configuration File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collect.xsession-errors</td>
<td>analyze_xsession_errors ccpp_event.conf</td>
<td>Saves relevant lines from the <code>~/.xsession-errors</code> file to the problem report.</td>
</tr>
<tr>
<td>Logger</td>
<td>report_LOGGER print_event.conf</td>
<td>Creates a problem report and saves it to a specified local file.</td>
</tr>
<tr>
<td>Kerneloops.org</td>
<td>report_Kerneloops koops_event.conf</td>
<td>Sends a kernel problem to the oops tracker at kerneloops.org.</td>
</tr>
</tbody>
</table>
The abrt-ccpp service has been used, provided the crashed application had any X11 libraries loaded at the time of the crash:

```
EVENT=analyze_xsession_errors analyzer=CCpp dso_list=-.*/libX11.*
    test -f ~/.xsession-errors || { echo "No ~/.xsession-errors";
    exit 1; }
    test -r ~/.xsession-errors || { echo "Can't read ~/.xsession-errors";
    exit 1; }
    executable=`cat executable` &&
    base_executable=${executable##*/} &&
    grep -F -e "$base_executable" ~/.xsession-errors | tail -999 >xsession_errors &&
    echo "Element 'xsession_errors' saved"
```

The set of possible events is not definitive. System administrators can add events according to their need in the `/etc/libreport/events.d/` directory.

Currently, the following event names are provided with the standard ABRT and libreport installations:

**post-create**

This event is run by abrtd to process newly created problem-data directories. When the `post-create` event is run, abrtd checks whether the new problem data matches any of the already existing problem directories. If such a problem directory exists, it is updated and the new problem data is discarded. Note that if the script in any definition of the `post-create` event exits with a non-zero value, abrtd will terminate the process and will drop the problem data.

**notify, notify-dup**

The `notify` event is run following the completion of `post-create`. When the event is run, the user can be sure that the problem deserves their attention. The `notify-dup` is similar, except it is used for duplicate occurrences of the same problem.

**analyze_name_suffix**

where `name_suffix` is the replaceable part of the event name. This event is used to process collected data. For example, the `analyze_LocalGDB` event uses the GNU Debugger (GDB) utility to process the core dump of an application and produce a backtrace of the crash.

**collect_name_suffix**

...where `name_suffix` is the adjustable part of the event name. This event is used to collect additional information on problems.

**report_name_suffix**

...where `name_suffix` is the adjustable part of the event name. This event is used to report a problem.

### 23.3.3. Setting Up Automatic Reporting

ABRT can be configured to send initial anonymous reports, or µReports, of any detected issues or crashes automatically without any user interaction. When automatic reporting is turned on, the so-called µReport, which is normally sent at the beginning of the crash-reporting process, is sent immediately after a crash is detected. This prevents duplicate support cases based on identical crashes. To enable the autoreporting feature, issue the following command as root:
The above command sets the `AutoreportingEnabled` directive in the `/etc/abrt/abrt.conf` configuration file to `yes`. This system-wide setting applies to all users of the system. Note that by enabling this option, automatic reporting will also be enabled in the graphical desktop environment. To only enable autoreporting in the ABRT GUI, switch the `Automatically send uReport` option to `YES` in the Problem Reporting Configuration window. To open this window, choose Automatic Bug Reporting Tool → ABRT Configuration from within a running instance of the `gnome-abrt` application. To launch the application, go to Applications → Sundry → Automatic Bug Reporting Tool.

![Problem Reporting Configuration](image)

Figure 23.2. Configuring ABRT Problem Reporting

Upon detection of a crash, by default, ABRT submits a μReport with basic information about the problem to Red Hat's ABRT server. The server determines whether the problem is known and either provides a short description of the problem along with a URL of the reported case if known, or invites the user to report it if not known.
NOTE

A μReport (microreport) is a JSON object representing a problem, such as a binary crash or a kernel oops. These reports are designed to be brief, machine readable, and completely anonymous, which is why they can be used for automated reporting. The μReports make it possible to keep track of bug occurrences, but they usually do not provide enough information for engineers to fix the bug. A full bug report is needed for a support case to be opened.

To change the default behavior of the autoreporting facility from sending a μReport, modify the value of the AutoreportingEvent directive in the /etc/abrt/abrt.conf configuration file to point to a different ABRT event. See Table 23.1, “Standard ABRT Events” for an overview of the standard events.

23.4. DETECTING SOFTWARE PROBLEMS

ABRT is capable of detecting, analyzing, and processing crashes in applications written in a variety of different programming languages. Many of the packages that contain the support for detecting the various types of crashes are installed automatically when either one of the main ABRT packages (abrt-desktop, abrt-cli) is installed. See Section 23.2, “Installing ABRT and Starting its Services” for instructions on how to install ABRT. See the table below for a list of the supported types of crashes and the respective packages.

Table 23.2. Supported Programming Languages and Software Projects

<table>
<thead>
<tr>
<th>Language/Project</th>
<th>Package</th>
</tr>
</thead>
<tbody>
<tr>
<td>C or C++</td>
<td>abrt-addon-ccpp</td>
</tr>
<tr>
<td>Python</td>
<td>abrt-addon-python</td>
</tr>
<tr>

</tr>
<tr>
<td>Linux (kernel panic)</td>
<td>abrt-addon-vmcore</td>
</tr>
<tr>
<td>Linux (persistent storage)</td>
<td>abrt-addon-pstoreoops</td>
</tr>
</tbody>
</table>

23.4.1. Detecting C and C++ Crashes

The abrt-ccpp service installs its own core-dump handler, which, when started, overrides the default value of the kernel's core_pattern variable, so that C and C++ crashes are handled by abrtd. If you stop the abrt-ccpp service, the previously specified value of core_pattern is reinstated.

By default, the /proc/sys/kernel/core_pattern file contains the string core, which means that the kernel produces files with the core prefix in the current directory of the crashed process. The abrt-ccpp service overwrites the core_pattern file to contain the following command:
This command instructs the kernel to pipe the core dump to the `abrt-hook-ccpp` program, which stores it in ABRT's dump location and notifies the `abrtd` daemon of the new crash. It also stores the following files from the `/proc/PID/` directory (where `PID` is the ID of the crashed process) for debugging purposes: `maps`, `limits`, `cgroup`, `status`. See `proc(5)` for a description of the format and the meaning of these files.

### 23.4.2. Detecting Python Exceptions

The `abrt-addon-python` package installs a custom exception handler for Python applications. The Python interpreter then automatically imports the `abrt.pth` file installed in `/usr/lib64/python2.7/site-packages/`, which in turn imports `abrt_exception_handler.py`. This overrides Python's default `sys.excepthook` with a custom handler, which forwards unhandled exceptions to `abrtd` via its Socket API.

To disable the automatic import of site-specific modules, and thus prevent the ABRT custom exception handler from being used when running a Python application, pass the `-S` option to the Python interpreter:

```
~]$ python -S file.py
```

In the above command, replace `file.py` with the name of the Python script you want to execute without the use of site-specific modules.

### 23.4.3. Detecting Ruby Exceptions

The `rubygem-abrt` package registers a custom handler using the `at_exit` feature, which is executed when a program ends. This allows for checking for possible unhandled exceptions. Every time an unhandled exception is captured, the ABRT handler prepares a bug report, which can be submitted to Red Hat Bugzilla using standard ABRT tools.

### 23.4.4. Detecting Java Exceptions

The ABRT Java Connector is a JVM agent that reports uncaught Java exceptions to `abrtd`. The agent registers several JVMTI event callbacks and has to be loaded into the JVM using the `-agentlib` command line parameter. Note that the processing of the registered callbacks negatively impacts the performance of the application. Use the following command to have ABRT catch exceptions from a Java class:

```
~]$ java -agentlib:abrt-java-connector[=abrt=on] $MyClass -platform.jvmtiSupported true
```

In the above command, replace `$MyClass` with the name of the Java class you want to test. By passing the `abrt=on` option to the connector, you ensure that the exceptions are handled by `abrtd`. In case you want to have the connector output the exceptions to standard output, omit this option.

### 23.4.5. Detecting X.Org Crashes

The `abrt-xorg` service collects and processes information about crashes of the X.Org server from the `/var/log/Xorg.0.log` file. Note that no report is generated if a blacklisted X.Org module is loaded. Instead, a `not-reportable` file is created in the `problem-data` directory with an appropriate...
explanation. You can find the list of offending modules in the /etc/abrt/plugins/xorg.conf file. Only proprietary graphics-driver modules are blacklisted by default.

23.4.6. Detecting Kernel Ooopses and Panics

By checking the output of kernel logs, ABRT is able to catch and process the so-called kernel oopses—non-fatal deviations from the correct behavior of the Linux kernel. This functionality is provided by the abrt-oops service.

ABRT can also detect and process kernel panics—fatal, non-recoverable errors that require a reboot, using the abrt-vmcore service. The service only starts when a vmcore file (a kernel-core dump) appears in the /var/crash/ directory. When a core-dump file is found, abrt-vmcore creates a new problem-data directory in the /var/tmp/abrt/ directory and moves the core-dump file to the newly created problem-data directory. After the /var/crash/ directory is searched, the service is stopped.

For ABRT to be able to detect a kernel panic, the kdump service must be enabled on the system. The amount of memory that is reserved for the kdump kernel has to be set correctly. You can set it using the system-config-kdump graphical tool or by specifying the crashkernel parameter in the list of kernel options in the GRUB menu. For details on how to enable and configure kdump, see the Red Hat Enterprise Linux 7 Kernel Crash Dump Guide. For information on making changes to the GRUB menu see Chapter 25, Working with GRUB 2.

Using the abrt-pstoreoops service, ABRT is capable of collecting and processing information about kernel panics, which, on systems that support pstore, is stored in the automatically-mounted /sys/fs/pstore/ directory. The platform-dependent pstore interface (persistent storage) provides a mechanism for storing data across system reboots, thus allowing for preserving kernel panic information. The service starts automatically when kernel crash-dump files appear in the /sys/fs/pstore/ directory.

23.5. HANDLING DETECTED PROBLEMS

Problem data saved by abrtd can be viewed, reported, and deleted using either the command line tool, abrt-cli, or the graphical tool, gnome-abrt.

NOTE

Note that ABRT identifies duplicate problems by comparing new problems with all locally saved problems. For a repeating crash, ABRT requires you to act upon it only once. However, if you delete the crash dump of that problem, the next time this specific problem occurs, ABRT will treat it as a new crash: ABRT will alert you about it, prompt you to fill in a description, and report it. To avoid having ABRT notifying you about a recurring problem, do not delete its problem data.

23.5.1. Using the Command Line Tool

In the command line environment, the user is notified of new crashes on login, provided they have the abrtn/console-notification package installed. The console notification looks like the following:

```
ABRT has detected 1 problem(s). For more info run: abrt-cli list --since 1398783164
```

To view detected problems, enter the `abrt-cli list` command:
```bash
$ abrt-cli list
id 6734c6f1a1ed169500a7bfc8bd62aabaf039f9aa
count: 1
executable: /usr/bin/sleep
package: coreutils-8.22-11.el7
time: Mon 21 Apr 2014 09:47:51 AM EDT
uid: 1000
```

Each crash listed in the output of the `abrt-cli list` command has a unique identifier and a directory that can be used for further manipulation using `abrt-cli`.

To view information about just one particular problem, use the `abrt-cli info` command:

```bash
abrt-cli info [-d] directory_or_id
```

To increase the amount of information displayed when using both the `list` and `info` sub-commands, pass them the `-d` (`--detailed`) option, which shows all stored information about the problems listed, including respective backtrace files if they have already been generated.

To analyze and report a certain problem, use the `abrt-cli report` command:

```bash
abrt-cli report directory_or_id
```

Upon invocation of the above command, you will be asked to provide your credentials for opening a support case with Red Hat Customer Support. Next, `abrt-cli` opens a text editor with the content of the report. You can see what is being reported, and you can fill in instructions on how to reproduce the crash and other comments. You should also check the backtrace because the backtrace might be sent to a public server and viewed by anyone, depending on the problem-reporter event settings.

**NOTE**
You can choose which text editor is used to check the reports. `abrt-cli` uses the editor defined in the `ABRT_EDITOR` environment variable. If the variable is not defined, it checks the `VISUAL` and `EDITOR` variables. If none of these variables is set, the `vi` editor is used. You can set the preferred editor in your `.bashrc` configuration file. For example, if you prefer GNU Emacs, add the following line to the file:

```bash
export VISUAL=emacs
```

When you are done with the report, save your changes and close the editor. If you have reported your problem to the Red Hat Customer Support database, a problem case is filed in the database. From now on, you will be informed about the problem-resolution progress via email you provided during the process of reporting. You can also monitor the problem case using the URL that is provided to you when the problem case is created or via emails received from Red Hat Support.

If you are certain that you do not want to report a particular problem, you can delete it. To delete a problem, so that ABRT does not keep information about it, use the command:

```bash
abrt-cli rm directory_or_id
```
To display help about a particular `abrt-cli` command, use the `--help` option:

```
  abrt-cli command --help
```

### 23.5.2. Using the GUI

The **ABRT** daemon broadcasts a **D-Bus** message whenever a problem report is created. If the **ABRT** applet is running in a graphical desktop environment, it catches this message and displays a notification dialog on the desktop. You can open the **ABRT** GUI using this dialog by clicking on the **Report** button. You can also open the **ABRT** GUI by selecting the **Applications → Sundry → Automatic Bug Reporting Tool** menu item.

Alternatively, you can run the **ABRT** GUI from the command line as follows:

```
  ~]$ gnome-abrt &
```

The **ABRT** GUI window displays a list of detected problems. Each problem entry consists of the name of the failing application, the reason why the application crashed, and the date of the last occurrence of the problem.

![Figure 23.3. ABRT GUI](image)

To access a detailed problem description, double-click on a problem-report line or click on the **Report** button while the respective problem line is selected. You can then follow the instructions to proceed with the process of describing the problem, determining how it should be analyzed, and where it should be reported. To discard a problem, click on the **Delete** button.

### 23.6. ADDITIONAL RESOURCES

For more information about **ABRT** and related topics, see the resources listed below.

**Installed Documentation**

- `abrtd(8)` — The manual page for the `abrtd` daemon provides information about options that can be used with the daemon.
abrt_event.conf(5) – The manual page for the abrt_event.conf configuration file describes the format of its directives and rules and provides reference information about event metadata configuration in XML files.

Online Documentation

- Red Hat Enterprise Linux 7 Networking Guide – The Networking Guide for Red Hat Enterprise Linux 7 documents relevant information regarding the configuration and administration of network interfaces and network services on this system.

- Red Hat Enterprise Linux 7 Kernel Crash Dump Guide – The Kernel Crash Dump Guide for Red Hat Enterprise Linux 7 documents how to configure, test, and use the kdump crash recovery service and provides a brief overview of how to analyze the resulting core dump using the crash debugging utility.

See Also

- Chapter 21, Viewing and Managing Log Files describes the configuration of the rsyslog daemon and the systemd journal and explains how to locate, view, and monitor system logs.

- Chapter 8, Yum describes how to use the Yum package manager to search, install, update, and uninstall packages on the command line.

- Chapter 9, Managing Services with systemd provides an introduction to systemd and documents how to use the systemctl command to manage system services, configure systemd targets, and execute power management commands.
CHAPTER 24. OPROFILE

OProfile is a low overhead, system-wide performance monitoring tool. It uses the performance monitoring hardware on the processor to retrieve information about the kernel and executables on the system, such as when memory is referenced, the number of L2 cache requests, and the number of hardware interrupts received. On a Red Hat Enterprise Linux system, the `oprofile` package must be installed to use this tool.

Many processors include dedicated performance monitoring hardware. This hardware makes it possible to detect when certain events happen (such as the requested data not being in cache). The hardware normally takes the form of one or more counters that are incremented each time an event takes place. When the counter value increments, an interrupt is generated, making it possible to control the amount of detail (and therefore, overhead) produced by performance monitoring.

OProfile uses this hardware (or a timer-based substitute in cases where performance monitoring hardware is not present) to collect samples of performance-related data each time a counter generates an interrupt. These samples are periodically written out to disk; later, the data contained in these samples can then be used to generate reports on system-level and application-level performance.

Be aware of the following limitations when using OProfile:

- **Use of shared libraries**— Samples for code in shared libraries are not attributed to the particular application unless the `--separate=library` option is used.

- **Performance monitoring samples are inexact**— When a performance monitoring register triggers a sample, the interrupt handling is not precise like a divide by zero exception. Due to the out-of-order execution of instructions by the processor, the sample may be recorded on a nearby instruction.

- **opreport does not associate samples for inline functions properly**— `opreport` uses a simple address range mechanism to determine which function an address is in. Inline function samples are not attributed to the inline function but rather to the function the inline function was inserted into.

- **OProfile accumulates data from multiple runs**— OProfile is a system-wide profiler and expects processes to start up and shut down multiple times. Thus, samples from multiple runs accumulate. Use the command `opcontrol --reset` to clear out the samples from previous runs.

- **Hardware performance counters do not work on guest virtual machines**— Because the hardware performance counters are not available on virtual systems, you need to use the timer mode. Enter the command `opcontrol --deinit`, and then execute `modprobe oprofile timer=1` to enable the timer mode.

- **Non-CPU-limited performance problems**— OProfile is oriented to finding problems with CPU-limited processes. OProfile does not identify processes that are asleep because they are waiting on locks or for some other event to occur (for example an I/O device to finish an operation).

24.1. OVERVIEW OF TOOLS

Table 24.1, “OProfile Commands” provides a brief overview of the most commonly used tools provided with the `oprofile` package.
Table 24.1. OProfile Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ophelp</td>
<td>Displays available events for the system's processor along with a brief description of each.</td>
</tr>
<tr>
<td>opimport</td>
<td>Converts sample database files from a foreign binary format to the native format for the system. Only use this option when analyzing a sample database from a different architecture.</td>
</tr>
<tr>
<td>opannotate</td>
<td>Creates annotated source for an executable if the application was compiled with debugging symbols. See Section 24.6.4, “Using opannotate” for details.</td>
</tr>
<tr>
<td>opcontrol</td>
<td>Configures what data is collected. See Section 24.3, “Configuring OProfile Using Legacy Mode” for details.</td>
</tr>
<tr>
<td>operf</td>
<td>Recommended tool to be used in place of opcontrol for profiling. See Section 24.2, “Using operf” for details. For differences between operf and opcontrol see Section 24.1.1, “operf vs. opcontrol”.</td>
</tr>
<tr>
<td>opreport</td>
<td>Retrieves profile data. See Section 24.6.1, “Using opreport” for details.</td>
</tr>
<tr>
<td>oprofiled</td>
<td>Runs as a daemon to periodically write sample data to disk.</td>
</tr>
</tbody>
</table>

24.1.1. operf vs. opcontrol

There are two mutually exclusive methods for collecting profiling data with OProfile. You can either use the newer and preferred operf or the opcontrol tool.

**operf**

This is the recommended mode for profiling. The operf tool uses the Linux Performance Events Subsystem, and therefore does not require the oprofile kernel driver. The operf tool allows you to target your profiling more precisely, as a single process or system-wide, and also allows OProfile to co-exist better with other tools using the performance monitoring hardware on your system. Unlike opcontrol, it can be used without the root privileges. However, operf is also capable of system-wide operations with use of the --system-wide option, where root authority is required.

With operf, there is no initial setup needed. You can invoke operf with command-line options to specify your profiling settings. After that, you can run the OProfile post-processing tools described in Section 24.6, “Analyzing the Data”. See Section 24.2, “Using operf” for further information.

**opcontrol**

This mode consists of the opcontrol shell script, the oprofiled daemon, and several post-processing tools. The opcontrol command is used for configuring, starting, and stopping a profiling session. An OProfile kernel driver, usually built as a kernel module, is used for collecting samples, which are then recorded into sample files by oprofiled. You can use legacy mode only if you have root privileges. In certain cases, such as when you need to sample areas with disabled interrupt request (IRQ), this is a better alternative.
Before OProfile can be run in legacy mode, it must be configured as shown in Section 24.3, “Configuring OProfile Using Legacy Mode”. These settings are then applied when starting OProfile (Section 24.4, “Starting and Stopping OProfile Using Legacy Mode”).

24.2. USING OPERF

operf is the recommended profiling mode that does not require initial setup before starting. All settings are specified as command-line options and there is no separate command to start the profiling process. To stop operf, press Ctrl+C. The typical operf command syntax looks as follows:

```
operf options range command args
```

Replace options with the desired command-line options to specify your profiling settings. Full set of options is described in operf(1) manual page. Replace range with one of the following:

- `--system-wide` - this setting allows for global profiling, see Note
- `--pid=PID` - this is to profile a running application, where PID is the process ID of the process you want to profile.

With command and args, you can define a specific command or application to be profiled, and also the input arguments that this command or application requires. Either command, --pid or --system-wide is required, but these cannot be used simultaneously.

When you invoke operf on a command line without setting the range option, data will be collected for the children processes.

NOTE

To run operf --system-wide, you need root authority. When finished profiling, you can stop operf with Ctrl+C.

If you run operf --system-wide as a background process (with &), stop it in a controlled manner in order to process the collected profile data. For this purpose, use:

```
kill -SIGINT operf-PID
```

When running operf --system-wide, it is recommended that your current working directory is /root or a subdirectory of /root so that sample data files are not stored in locations accessible by regular users.

24.2.1. Specifying the Kernel

To monitor the kernel, execute the following command:

```
operf --vmlinux=vmlinux_path
```

With this option, you can specify a path to a vmlinux file that matches the running kernel. Kernel samples will be attributed to this binary, allowing post-processing tools to attribute samples to the appropriate kernel symbols. If this option is not specified, all kernel samples will be attributed to a pseudo binary named "no-vmlinux".
24.2.2. Setting Events to Monitor

Most processors contain counters, which are used by OProfile to monitor specific events. As shown in Table 24.3, “OProfile Processors and Counters”, the number of counters available depends on the processor.

The events for each counter can be configured via the command line or with a graphical interface. For more information on the graphical interface, see Section 24.10, “Graphical Interface”. If the counter cannot be set to a specific event, an error message is displayed.

**NOTE**

Some older processor models are not supported by the underlying Linux Performance Events Subsystem kernel and therefore are not supported by *operf*. If you receive this message:

```
Your kernel's Performance Events Subsystem does not support your processor type
```

when attempting to use *operf*, try profiling with *opcontrol* to see if your processor type may be supported by OProfile's legacy mode.

**NOTE**

Since hardware performance counters are not available on guest virtual machines, you have to enable *timer* mode to use *operf* on virtual systems. To do so, type as *root*:

```
opcontrol --deinit

modprobe oprofile timer=1
```

To set the event for each configurable counter via the command line, use:

```
operf --events=event1,event2...
```

Here, pass a comma-separated list of event specifications for profiling. Each event specification is a colon-separated list of attributes in the following form:

```
event-name:sample-rate:unit-mask:kernel:user
```

Table 24.2, “Event Specifications” summarizes these options. The last three values are optional, if you omit them, they will be set to their default values. Note that certain events do require a unit mask.

Table 24.2. Event Specifications

<table>
<thead>
<tr>
<th>Specification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>event-name</em></td>
<td>The exact symbolic event name taken from <em>ophelp</em></td>
</tr>
</tbody>
</table>
The events available vary depending on the processor type. When no event specification is given, the default event for the running processor type will be used for profiling. See Table 24.4, “Default Events” for a list of these default events. To determine the events available for profiling, use the ophelp command.

### ophelp

24.2.3. Categorization of Samples

The --separate-thread option categorizes samples by thread group ID (tgid) and thread ID (tid). This is useful for seeing per-thread samples in multi-threaded applications. When used in conjunction with the --system-wide option, --separate-thread is also useful for seeing per-process (per-thread group) samples for the case where multiple processes are executing the same program during a profiling run.

The --separate-cpu option categorizes samples by CPU.

24.3. CONFIGURING OPROFILE USING LEGACY MODE

Before OProfile can be run in legacy mode, it must be configured. At a minimum, selecting to monitor the kernel (or selecting not to monitor the kernel) is required. The following sections describe how to
use the `opcontrol` utility to configure OProfile. As the `opcontrol` commands are executed, the setup options are saved to the `/root/.oprofile/daemonrc` file.

### 24.3.1. Specifying the Kernel

First, configure whether OProfile should monitor the kernel. This is the only configuration option that is required before starting OProfile. All others are optional.

To monitor the kernel, execute the following command as root:

```bash
opcontrol --setup --vmlinux=/usr/lib/debug/lib/modules/`uname -r`/vmlinux
```

**IMPORTANT**

In order to monitor the kernel, the `kernel-debuginfo` package which contains the uncompressed kernel must be installed. For more information on how to install this package, see the [How to download debuginfo packages like kernel-debuginfo?](https://www.redhat.com) article on the Red Hat Customer Portal.

To configure OProfile not to monitor the kernel, execute the following command as root:

```bash
opcontrol --setup --no-vmlinux
```

This command also loads the `oprofile` kernel module, if it is not already loaded, and creates the `/dev/oprofile/` directory, if it does not already exist. See [Section 24.7, “Understanding the /dev/oprofile/ directory”](#) for details about this directory.

Setting whether samples should be collected within the kernel only changes what data is collected, not how or where the collected data is stored. To generate different sample files for the kernel and application libraries, see [Section 24.3.3, “Separating Kernel and User-space Profiles”](#).

### 24.3.2. Setting Events to Monitor

Most processors contain counters, which are used by OProfile to monitor specific events. As shown in Table 24.3, “OProfile Processors and Counters”, the number of counters available depends on the processor.

<table>
<thead>
<tr>
<th>Processor</th>
<th>cpu_type</th>
<th>Number of Counters</th>

Use Table 24.3, “OProfile Processors and Counters” to determine the number of events that can be monitored simultaneously for your CPU type. If the processor does not have supported performance monitoring hardware, the timer is used as the processor type.

If timer is used, events cannot be set for any processor because the hardware does not have support for hardware performance counters. Instead, the timer interrupt is used for profiling.

If timer is not used as the processor type, the events monitored can be changed, and counter 0 for the processor is set to a time-based event by default. If more than one counter exists on the processor, the counters other than 0 are not set to an event by default. The default events monitored are shown in Table 24.4, “Default Events”.

</tbody>
</table>

The number of events that can be monitored at one time is determined by the number of counters for the processor. However, it is not a one-to-one correlation; on some processors, certain events must be mapped to specific counters. To determine the number of counters available, execute the following command:

```
ls -d /dev/oprofile/[0-9]*
```

The events available vary depending on the processor type. Use the ophelp command to determine the events available for profiling. The list is specific to the system's processor type.

```
ophelp
```
Note

Unless OProfile is properly configured, ophelp fails with the following error message:

```
Unable to open cpu_type file for reading
Make sure you have done opcontrol --init
cpu_type 'unset' is not valid
you should upgrade oprofile or force the use of timer mode
```

To configure OProfile, follow the instructions in Section 24.3, “Configuring OProfile Using Legacy Mode”.

The events for each counter can be configured via the command line or with a graphical interface. For more information on the graphical interface, see Section 24.10, “Graphical Interface”. If the counter cannot be set to a specific event, an error message is displayed.

To set the event for each configurable counter via the command line, use opcontrol:

```
opcontrol --event=event-name:sample-rate
```

Replace `event-name` with the exact name of the event from ophelp, and replace `sample-rate` with the number of events between samples.

24.3.2.1. Sampling Rate

By default, a time-based event set is selected. It creates a sample every 100,000 clock cycles per processor. If the timer interrupt is used, the timer is set to the respective rate and is not user-settable. If the `cpu_type` is not `timer`, each event can have a `sampling rate` set for it. The sampling rate is the number of events between each sample snapshot.

When setting the event for the counter, a sample rate can also be specified:

```
opcontrol --event=event-name:sample-rate
```

Replace `sample-rate` with the number of events to wait before sampling again. The smaller the count, the more frequent the samples. For events that do not happen frequently, a lower count may be needed to capture the event instances.

**Warning**

Be extremely careful when setting sampling rates. Sampling too frequently can overload the system, causing the system to appear frozen or causing the system to actually freeze.

24.3.2.2. Unit Masks

Some user performance monitoring events may also require unit masks to further define the event.
Unit masks for each event are listed with the `ophelp` command. The values for each unit mask are listed in hexadecimal format. To specify more than one unit mask, the hexadecimal values must be combined using a bitwise `or` operation.

```
  opcontrol --event=event-name:sample-rate:unit-mask
```

Note that on certain architectures, there can be multiple unit masks with the same hexadecimal value. In that case they have to be specified by their names only.

### 24.3.3. Separating Kernel and User-space Profiles

By default, kernel mode and user mode information is gathered for each event. To configure OProfile to ignore events in kernel mode for a specific counter, execute the following command:

```
  opcontrol --event=event-name:sample-rate:unit-mask:0
```

Execute the following command to start profiling kernel mode for the counter again:

```
  opcontrol --event=event-name:sample-rate:unit-mask:1
```

To configure OProfile to ignore events in user mode for a specific counter, execute the following command:

```
  opcontrol --event=event-name:sample-rate:unit-mask:1:0
```

Execute the following command to start profiling user mode for the counter again:

```
  opcontrol --event=event-name:sample-rate:unit-mask:1:1
```

When the OProfile daemon writes the profile data to sample files, it can separate the kernel and library profile data into separate sample files. To configure how the daemons writes to sample files, execute the following command as root:

```
  opcontrol --separate=choice
```

The `choice` argument can be one of the following:

- **none** — Do not separate the profiles (default).
- **library** — Generate per-application profiles for libraries.
- **kernel** — Generate per-application profiles for the kernel and kernel modules.
- **all** — Generate per-application profiles for libraries and per-application profiles for the kernel and kernel modules.

If `--separate=library` is used, the sample file name includes the name of the executable as well as the name of the library.

NOTE

These configuration changes will take effect when the OProfile profiler is restarted.
24.4. STARTING AND STOPPING OPROFILE USING LEGACY MODE

To start monitoring the system with OProfile, execute the following command as root:

```
opcontrol --start
```

Output similar to the following is displayed:

```
The settings in /root/.oprofile/daemonrc are used.
```

The OProfile daemon, `oprofiled`, is started; it periodically writes the sample data to the `/var/lib/oprofile/samples/` directory. The log file for the daemon is located at `/var/lib/oprofile/oprofiled.log`.

**IMPORTANT**

On a Red Hat Enterprise Linux 7 system, the `nmi_watchdog` registers with the `perf` subsystem. Due to this, the `perf` subsystem grabs control of the performance counter registers at boot time, blocking OProfile from working.

To resolve this, either boot with the `nmi_watchdog=0` kernel parameter set, or run the following command as `root` to disable `nmi_watchdog` at run time:

```
echo 0 > /proc/sys/kernel/nmi_watchdog
```

To re-enable `nmi_watchdog`, use the following command as `root`:

```
echo 1 > /proc/sys/kernel/nmi_watchdog
```

To stop the profiler, execute the following command as root:

```
opcontrol --shutdown
```

24.5. SAVING DATA IN LEGACY MODE

Sometimes it is useful to save samples at a specific time. For example, when profiling an executable, it may be useful to gather different samples based on different input data sets. If the number of events to be monitored exceeds the number of counters available for the processor, multiple runs of OProfile can be used to collect data, saving the sample data to different files each time.

To save the current set of sample files, execute the following command, replacing `name` with a unique descriptive name for the current session:

```
opcontrol --save=name
```

The command creates the directory `/var/lib/oprofile/samples/name/` and the current sample files are copied to it.
To specify the session directory to hold the sample data, use the \texttt{--session-dir} option. If not specified, the data is saved in the \texttt{oprofile_data/} directory on the current path.

## 24.6. ANALYZING THE DATA

The same OProfile post-processing tools are used whether you collect your profile with \texttt{operf} or \texttt{opcontrol} in legacy mode.

By default, \texttt{operf} stores the profiling data in the \texttt{current_dir/oprofile_data/} directory. You can change to a different location with the \texttt{--session-dir} option. The usual post-profiling analysis tools such as \texttt{opreport} and \texttt{opannotate} can be used to generate profile reports. These tools search for samples in \texttt{current_dir/oprofile_data/} first. If this directory does not exist, the analysis tools use the standard session directory of \texttt{/var/lib/oprofile/}. Statistics, such as total samples received and lost samples, are written to the \texttt{session_dir/samples/operf.log} file.

When using legacy mode, the OProfile daemon, \texttt{oprofiled}, periodically collects the samples and writes them to the \texttt{/var/lib/oprofile/samples/} directory. Before reading the data, make sure all data has been written to this directory by executing the following command as root:

\begin{verbatim}
    opcontrol --dump
\end{verbatim}

Each sample file name is based on the name of the executable. For example, the samples for the default event on a Pentium III processor for \texttt{/bin/bash} becomes:

\begin{verbatim}
    \{root\}/bin/bash/\{dep\}/\{root\}/bin/bash/CPU_CLK_UNHALTED.100000
\end{verbatim}

The following tools are available to profile the sample data once it has been collected:

- \texttt{opreport}
- \texttt{opannotate}

Use these tools, along with the binaries profiled, to generate reports that can be further analyzed.

\begin{warning}

The executable being profiled must be used with these tools to analyze the data. If it must change after the data is collected, back up the executable used to create the samples as well as the sample files. Note that the names of the sample file and the binary have to agree. You cannot make a backup if these names do not match. As an alternative, \texttt{oparchive} can be used to address this problem.
\end{warning}

Samples for each executable are written to a single sample file. Samples from each dynamically linked library are also written to a single sample file. While OProfile is running, if the executable being monitored changes and a sample file for the executable exists, the existing sample file is automatically deleted. Thus, if the existing sample file is needed, it must be backed up, along with the executable used to create it before replacing the executable with a new version. The OProfile analysis tools use
the executable file that created the samples during analysis. If the executable changes, the analysis tools will be unable to analyze the associated samples. See Section 24.5, “Saving Data in Legacy Mode” for details on how to back up the sample file.

### 24.6.1. Using opreport

The **opreport** tool provides an overview of all the executables being profiled. The following is part of a sample output from the **opreport** command:

```
$ opreport
Profiling through timer interrupt
TIMER:0| samples| %|
------------------
25926 97.5212 no-vmlinuz
359 1.3504  pi
65 0.2445  Xorg
62 0.2332  libvte.so.4.4.0
56 0.2106  libc-2.3.4.so
34 0.1279  libglib-2.0.so.0.400.7
19 0.0715  libXft.so.2.1.2
17 0.0639  bash
8 0.0301   ld-2.3.4.so
8 0.0301   libgdk-x11-2.0.so.0.400.13
6 0.0226   libgobject-2.0.so.0.400.7
5 0.0188   oprofiled
4 0.0150   libpthread-2.3.4.so
4 0.0150   libgtk-x11-2.0.so.0.400.13
3 0.0113   libXrender.so.1.2.2
3 0.0113   du
1 0.0038   libcrypto.so.0.9.7a
1 0.0038   libpam.so.0.77
1 0.0038   libtermcap.so.2.0.8
1 0.0038   libXi.so.6.2
1 0.0038   libgthread-2.0.so.0.400.7
1 0.0038   libwnck-1.so.4.9.0
```

Each executable is listed on its own line. The first column is the number of samples recorded for the executable. The second column is the percentage of samples relative to the total number of samples. The third column is the name of the executable.

See the **opreport**(1) manual page for a list of available command-line options, such as the **-r** option used to sort the output from the executable with the smallest number of samples to the one with the largest number of samples. You can also use the **-t** or **--threshold** option to trim the output of **opcontrol**.

### 24.6.2. Using opreport on a Single Executable

To retrieve more detailed profiled information about a specific executable, use:

```
$ opreport mode executable
```

Replace **executable** with the full path to the executable to be analyzed. **mode** stands for one of the following options:
This option is used to list sample data by symbols. For example, running this command:

```bash
~ ]# opreport -l /usr/lib/tls/libc-version.so
```

produces the following output:

```
samples % symbol name
12 21.4286 __gconv_translate_utf8_internal
  5 8.9286 _int_malloc 4 7.1429 malloc
  3 5.3571 __i686.get_pc_thunk.bx
  3 5.3571 __dl_mcount_wrapper_check
  3 5.3571 mbtowc
  3 5.3571 memcpy
  2 3.5714 _int_free
  2 3.5714 strcspn
  1 1.7857 __ctype_get_mb_cur_max
  1 1.7857 __unregister_atfork
  1 1.7857 __write_nocancel
  1 1.7857 __dl_addr
  1 1.7857 __malloc
  1 1.7857 __malloc
  1 1.7857 __memmove
  1 1.7857 msort_with_tmp
  1 1.7857 memcpy
  1 1.7857 memmove
  1 1.7857 strlen
  1 1.7857 vfprintf
  1 1.7857 write
```

The first column is the number of samples for the symbol, the second column is the percentage of samples for this symbol relative to the overall samples for the executable, and the third column is the symbol name.

To sort the output from the largest number of samples to the smallest (reverse order), use `-r` in conjunction with the `-l` option.

```
-i symbol-name
```

List sample data specific to a symbol name. For example, running:

```bash
~ ]# opreport -l -i __gconv_translate_utf8_internal /usr/lib/tls/libc-version.so
```

returns the following output:

```
samples % symbol name
12 100.000 __gconv_translate_utf8_internal
```

The first line is a summary for the symbol/executable combination.
The first column is the number of samples for the memory symbol. The second column is the percentage of samples for the memory address relative to the total number of samples for the symbol. The third column is the symbol name.

-d

This option lists sample data by symbols with more detail than the -l option. For example, with the following command:

```
[~]# opreport -d -i __gconv_transform_utf8_internal /usr/lib/tls/libc-version.so
```

this output is returned:

```
vma samples % symbol name
00a98640 12 100.000 __gconv_transform_utf8_internal
00a98640  1  8.3333
00a9868c  2  16.6667
00a9869a  1  8.3333
00a986c1  1  8.3333
00a98720  1  8.3333
00a98749  1  8.3333
00a98753  1  8.3333
00a98789  1  8.3333
00a98864  1  8.3333
00a98869  1  8.3333
00a98b08  1  8.3333
```

The data is the same as the -l option except that for each symbol, each virtual memory address used is shown. For each virtual memory address, the number of samples and percentage of samples relative to the number of samples for the symbol is displayed.

-e symbol-name...

With this option, you can exclude some symbols from the output. Replace symbol-name with the comma-separated list of symbols you want to exclude.

session: name

Here, you can specify the full path to the session, a directory relative to the /var/lib/oprofile/samples/ directory, or if you are using operf, a directory relative to ./oprofile_data/samples/.

24.6.3. Getting More Detailed Output on the Modules

OProfile collects data on a system-wide basis for kernel- and user-space code running on the machine. However, once a module is loaded into the kernel, the information about the origin of the kernel module is lost. The module could come from the initrd file on boot up, the directory with the various kernel modules, or a locally created kernel module. As a result, when OProfile records samples for a module, it just lists the samples for the modules for an executable in the root directory, but this is unlikely to be the place with the actual code for the module. You will need to take some steps to make sure that analysis tools get the proper executable.
To get a more detailed view of the actions of the module, you will need to either have the module "unstripped" (that is installed from a custom build) or have the debuginfo package installed for the kernel.

Find out which kernel is running with the `uname -a` command, obtain the appropriate debuginfo package and install it on the machine.

Then proceed with clearing out the samples from previous runs with the following command:

```
  opcontrol --reset
```

To start the monitoring process, for example, on a machine with Westmere processor, run the following command:

```
  ~]# opcontrol --setup --vmlinux=/usr/lib/debug/lib/modules/`uname -r`/vmlinux --event=CPU_CLK_UNHALTED:500000
```

Then the detailed information, for instance, for the ext4 module can be obtained with:

```
  ~]# opreport /ext4 -l --image-path /usr/lib/modules/`uname -r`/kernel
CPU: Intel Westmere microarchitecture, speed 2.667e+06 MHz (estimated)
Counted CPU_CLK_UNHALTED events (Clock cycles when not halted) with a unit
mask of 0x00 (No unit mask) count 500000
warning: could not check that the binary file /lib/modules/2.6.32-191.el6.x86_64/kernel/fs/ext4/ext4.ko has not been modified since the
profile was taken. Results may be inaccurate.
samples  %        symbol name
  1622    9.8381  ext4_iget
  1591    9.6500  ext4_find_entry
  1231    7.4665  __ext4_get_inode_loc
   783    4.7492  ext4_ext_get_blocks
   752    4.5612  ext4_check_dir_entry
   644    3.9061  ext4_mark_iloc_dirty
   583    3.5361  ext4_get_blocks
   583    3.5361  ext4_xattr_get
   479    2.9053  ext4_htree_store_dirent
   469    2.8447  ext4_get_group_desc
   414    2.5111  ext4_dx_find_entry
```

### 24.6.4. Using opannotate

The opannotate tool tries to match the samples for particular instructions to the corresponding lines in the source code. The resulting generated files should have the samples for the lines at the left. It also puts in a comment at the beginning of each function listing the total samples for the function.

For this utility to work, the appropriate debuginfo package for the executable must be installed on the system. On Red Hat Enterprise Linux, the debuginfo packages are not automatically installed with the corresponding packages that contain the executable. You have to obtain and install them separately.

The general syntax for opannotate is as follows:

```
  opannotate --search-dirs src-dir --source executable
```
These command-line options are mandatory. Replace `src-dir` with a path to the directory containing the source code and specify the executable to be analyzed. See the `opannotate(1)` manual page for a list of additional command line options.

### 24.7. UNDERSTANDING THE /DEV/OPROFILE/ DIRECTORY

When using OProfile in legacy mode, the `/dev/oprofile/` directory is used to store the file system for OProfile. On the other hand, `operf` does not require `/dev/oprofile/`. Use the `cat` command to display the values of the virtual files in this file system. For example, the following command displays the type of processor OProfile detected:

```
cat /dev/oprofile/cpu_type
```

A directory exists in `/dev/oprofile/` for each counter. For example, if there are 2 counters, the directories `/dev/oprofile/0/` and `/dev/oprofile/1/` exist.

Each directory for a counter contains the following files:

- **count** – The interval between samples.
- **enabled** – If 0, the counter is off and no samples are collected for it; if 1, the counter is on and samples are being collected for it.
- **event** – The event to monitor.
- **extra** – Used on machines with Nehalem processors to further specify the event to monitor.
- **kernel** – If 0, samples are not collected for this counter event when the processor is in kernel-space; if 1, samples are collected even if the processor is in kernel-space.
- **unit_mask** – Defines which unit masks are enabled for the counter.
- **user** – If 0, samples are not collected for the counter event when the processor is in user-space; if 1, samples are collected even if the processor is in user-space.

The values of these files can be retrieved with the `cat` command. For example:

```
cat /dev/oprofile/0/count
```

### 24.8. EXAMPLE USAGE

While OProfile can be used by developers to analyze application performance, it can also be used by system administrators to perform system analysis. For example:

- **Determine which applications and services are used the most on a system** – `opreport` can be used to determine how much processor time an application or service uses. If the system is used for multiple services but is underperforming, the services consuming the most processor time can be moved to dedicated systems.

- **Determine processor usage** – The `CPU_CLK_UNHALTED` event can be monitored to determine the processor load over a given period of time. This data can then be used to determine if additional processors or a faster processor might improve system performance.
24.9. OPROFILE SUPPORT FOR JAVA

OProfile allows you to profile dynamically compiled code (also known as "just-in-time" or JIT code) of the Java Virtual Machine (JVM). OProfile in Red Hat Enterprise Linux 7 includes built-in support for the JVM Tools Interface (JVMTI) agent library, which supports Java 1.5 and higher.

24.9.1. Profiling Java Code

To profile JIT code from the Java Virtual Machine with the JVMTI agent, add the following to the JVM startup parameters:

```
-agentlib:jvmti_oprofile
```

Where `jvmti_oprofile` is a path to the OProfile agent. For 64-bit JVM, the path looks as follows:

```
-agentlib:/usr/lib64/oprofile/libjvmti_oprofile.so
```

Currently, you can add one command-line option: `-debug`, which enables debugging mode.

**NOTE**

The `oprofile-jit` package must be installed on the system in order to profile JIT code with OProfile. With this package, you gain the capability to show method-level information.

Depending on the JVM that you are using, you may have to install the `debuginfo` package for the JVM. For OpenJDK, this package is required, there is no debuginfo package for Oracle JDK. To keep the debug information packages synchronized with their respective non-debug packages, you also need to install the `yum-plugin-auto-update-debug-info` plug-in. This plug-in searches the debug information repository for corresponding updates.

After successful setup, you can apply the standard profiling and analyzing tools described in previous sections.

To learn more about Java support in OProfile, see the OProfile Manual, which is linked from Section 24.12, “Additional Resources”.

24.10. GRAPHICAL INTERFACE

Some OProfile preferences can be set with a graphical interface. Make sure you have the `oprofile-gui` package that provides the OProfile GUI installed on your system. To start the interface, execute the `oprof_start` command as root at a shell prompt.

After changing any of the options, save them by clicking the **Save and quit** button. The preferences are written to `/root/.oprofile/daemonrc`, and the application exits.

**NOTE**

Exiting the application does not stop OProfile from sampling.

On the **Setup** tab, to set events for the processor counters as discussed in Section 24.3.2, “Setting Events to Monitor”, select the counter from the pulldown menu and select the event from the list. A brief description of the event appears in the text box below the list. Only events available for the
specific counter and the specific architecture are displayed. The interface also displays whether the profiler is running and some brief statistics about it.

Figure 24.1. OPProfile Setup

On the right side of the tab, select the Profile kernel option to count events in kernel mode for the currently selected event, as discussed in Section 24.3.3, “Separating Kernel and User-space Profiles”. If this option is not selected, no samples are collected for the kernel.

Select the Profile user binaries option to count events in user mode for the currently selected event, as discussed in Section 24.3.3, “Separating Kernel and User-space Profiles”. If this option is not selected, no samples are collected for user applications.
Use the Count text field to set the sampling rate for the currently selected event as discussed in Section 24.3.2.1, “Sampling Rate”.

If any unit masks are available for the currently selected event, as discussed in Section 24.3.2.2, “Unit Masks”, they are displayed in the Unit Masks area on the right side of the Setup tab. Select the check box beside the unit mask to enable it for the event.

On the Configuration tab, to profile the kernel, enter the name and location of the vmlinux file for the kernel to monitor in the Kernel image file text field. To configure OProfile not to monitor the kernel, select No kernel image.

![Figure 24.2. OProfile Configuration](image-url)
If the **Verbose** option is selected, the **oprofiled** daemon log includes more detailed information.

If **Per-application profiles** is selected, OProfile generates per-application profiles for libraries. This is equivalent to the `opcontrol --separate=library` command. If **Per-application profiles, including kernel** is selected, OProfile generates per-application profiles for the kernel and kernel modules as discussed in Section 24.3.3, “Separating Kernel and User-space Profiles”. This is equivalent to the `opcontrol --separate=kernel` command.

To force data to be written to samples files as discussed in Section 24.6, “Analyzing the Data”, click the **Flush** button. This is equivalent to the `opcontrol --dump` command.

To start OProfile from the graphical interface, click **Start**. To stop the profiler, click **Stop**. Exiting the application does not stop OProfile from sampling.

**24.11. OPROFILE AND SYSTEMTAP**

SystemTap is a tracing and probing tool that allows users to study and monitor the activities of the operating system in fine detail. It provides information similar to the output of tools like `netstat`, `ps`, `top`, and `iostat`; however, SystemTap is designed to provide more filtering and analysis options for the collected information.

While using OProfile is suggested in cases of collecting data on where and why the processor spends time in a particular area of code, it is less usable when finding out why the processor stays idle.

You might want to use SystemTap when instrumenting specific places in code. Because SystemTap allows you to run the code instrumentation without having to stop and restart the instrumented code, it is particularly useful for instrumenting the kernel and daemons.

For more information on SystemTap, see [SystemTap Beginners Guide](#).

**24.12. ADDITIONAL RESOURCES**

To learn more about OProfile and how to configure it, see the following resources.

**Installed Documentation**

- `oprofile(1)` manual page — Discusses `opcontrol`, `opreport`, `opannotate`, and `ophelp`
- `operf(1)` manual page

**Online Documentation**

- [http://oprofile.sourceforge.net/](http://oprofile.sourceforge.net/) — upstream documentation that contains documentation, mailing lists, IRC channels, and more about the OProfile project. In Red Hat Enterprise Linux 7, OProfile version 0.9.9. is provided.

**See Also**

- [SystemTap Beginners Guide](#) — Provides basic instructions on how to use SystemTap to monitor different subsystems of Red Hat Enterprise Linux in finer detail.
PART VII. KERNEL, MODULE AND DRIVER CONFIGURATION

This part covers various tools that assist administrators with kernel customization.
CHAPTER 25. WORKING WITH GRUB 2

Red Hat Enterprise Linux 7 is distributed with version 2 of the GNU GRand Unified Bootloader (GRUB 2), which allows the user to select an operating system or kernel to be loaded at system boot time. GRUB 2 also allows the user to pass arguments to the kernel.

25.1. INTRODUCTION TO GRUB 2

GRUB 2 reads its configuration from the /boot/grub2/grub.cfg file on traditional BIOS-based machines and from the /boot/efi/EFI/redhat/grub.cfg file on UEFI machines. This file contains menu information.

The GRUB 2 configuration file, grub.cfg, is generated during installation, or by invoking the /usr/sbin/grub2-mkconfig utility, and is automatically updated by grubby each time a new kernel is installed. When regenerated manually using grub2-mkconfig, the file is generated according to the template files located in /etc/grub.d/, and custom settings in the /etc/default/grub file. Edits of grub.cfg will be lost anytime grub2-mkconfig is used to regenerate the file, so care must be taken to reflect any manual changes in /etc/default/grub as well.

Normal operations on grub.cfg, such as the removal and addition of new kernels, should be done using the grubby tool and, for scripts, using new-kernel-pkg tool. If you use grubby to modify the default kernel the changes will be inherited when new kernels are installed. For more information on grubby, see Section 25.4, “Making Persistent Changes to a GRUB 2 Menu Using the grubby Tool”.

The /etc/default/grub file is used by the grub2-mkconfig tool, which is used by anaconda when creating grub.cfg during the installation process, and can be used in the event of a system failure, for example if the boot loader configurations need to be recreated. In general, it is not recommended to replace the grub.cfg file by manually running grub2-mkconfig except as a last resort. Note that any manual changes to /etc/default/grub require rebuilding the grub.cfg file.

Menu Entries in grub.cfg

Among various code snippets and directives, the grub.cfg configuration file contains one or more menuentry blocks, each representing a single GRUB 2 boot menu entry. These blocks always start with the menuentry keyword followed by a title, list of options, and an opening curly bracket, and end with a closing curly bracket. Anything between the opening and closing bracket should be indented. For example, the following is a sample menuentry block for Red Hat Enterprise Linux 7 with Linux kernel 3.8.0-40.el7.x86_64:

```
menuentry 'Red Hat Enterprise Linux Server' --class red --class gnu-linux --class gnu --class os $menuentry_id_option 'gnulinux-simple-c60731dc-9046-4000-9182-64bdce08616' {
    load_video
    set gfxpayload=keep
    insmod gzip
    insmod part_msdos
    insmod xfs
    set root='hd0,msdos1'
    if [ x$feature_platform_search_hint = xy ]; then
        search --no-floppy --fs-uuid --set=root --hint-bios=hd0,msdos1 - -hint-efi=hd0,msdos1 --hint-baremetal=ahci0,msdos1 --hint='hd0,msdos1'
        19d9e294-65f8-4e37-8e73-d41d6daa6e58
    else
        search --no-floppy --fs-uuid --set=root 19d9e294-65f8-4e37-8e73-d41d6daa6e58
```
Each menuentry block that represents an installed Linux kernel contains _linux_ on 64-bit IBM POWER Series, _linux16_ on x86_64 BIOS-based systems, and _linuxefi_ on UEFI-based systems. Then the _initrd_ directives followed by the path to the kernel and the _initramfs_ image respectively. If a separate _/boot_ partition was created, the paths to the kernel and the _initramfs_ image are relative to _/boot_. In the example above, the _initrd_ _/initramfs-3.8.0-0.40.el7.x86_64.img_ line means that the _initramfs_ image is actually located at _/boot/initramfs-3.8.0-0.40.el7.x86_64.img_ when the root file system is mounted, and likewise for the kernel path.

The kernel version number as given on the _linux16_ _/vmlinuz-kernel_version_ line must match the version number of the _initramfs_ image given on the _initrd_ _/initramfs-kernel_version.img_ line of each menuentry block. For more information on how to verify the initial RAM disk image, see Section 26.5, “Verifying the Initial RAM Disk Image”.

**NOTE**

In menuentry blocks, the _initrd_ directive must point to the location (relative to the _/boot/_ directory if it is on a separate partition) of the _initramfs_ file corresponding to the same kernel version. This directive is called _initrd_ because the previous tool which created initial RAM disk images, mkinitrd, created what were known as _initrd_ files. The _grub.cfg_ directive remains _initrd_ to maintain compatibility with other tools. The file-naming convention of systems using the _dracut_ utility to create the initial RAM disk image is _initramfs-kernel_version.img_.

For information on using _Dracut_, see Section 26.5, “Verifying the Initial RAM Disk Image”.

### 25.2. CONFIGURING GRUB 2

Changes to the GRUB 2 menu can be made temporarily at boot time, made persistent for a single system while the system is running, or as part of making a new GRUB 2 configuration file.

- To make non-persistent changes to the GRUB 2 menu, see Section 25.3, “Making Temporary Changes to a GRUB 2 Menu”.

- To make persistent changes to a running system, see Section 25.4, “Making Persistent Changes to a GRUB 2 Menu Using the grubby Tool”.

- For information on making and customizing a GRUB 2 configuration file, see Section 25.5, “Customizing the GRUB 2 Configuration File”.

### 25.3. MAKING TEMPORARY CHANGES TO A GRUB 2 MENU

Procedure 25.1. Making Temporary Changes to a Kernel Menu Entry
To change kernel parameters only during a single boot process, proceed as follows:

1. Start the system and, on the GRUB 2 boot screen, move the cursor to the menu entry you want to edit, and press the `e` key for edit.

2. Move the cursor down to find the kernel command line. The kernel command line starts with `linux` on 64-Bit IBM Power Series, `linux16` on x86-64 BIOS-based systems, or `linuxefi` on UEFI systems.

3. Move the cursor to the end of the line.

   Press `Ctrl+a` and `Ctrl+e` to jump to the start and end of the line, respectively. On some systems, `Home` and `End` might also work.

4. Edit the kernel parameters as required. For example, to run the system in emergency mode, add the `emergency` parameter at the end of the `linux16` line:

   ```
   linux16 /vmlinuz-3.10.0-0.rc4.59.el7.x86_64
   root=/dev/mapper/rhel-root ro rd.md=0 rd.dm=0 rd.lvm.lv=rhel/swap
   crashkernel=auto rd.luks=0 vconsole.keymap=us rd.lvm.lv=rhel/root
   rhgb quiet emergency
   ```

   The `rhgb` and `quiet` parameters can be removed in order to enable system messages.

   These settings are not persistent and apply only for a single boot. To make persistent changes to a menu entry on a system, use the `grubby` tool. See the section called “Adding and Removing Arguments from a GRUB Menu Entry” for more information on using `grubby`.

### 25.4. MAKING PERSISTENT CHANGES TO A GRUB 2 MENU USING THE GRUBBY TOOL

The `grubby` tool can be used to read information from, and make persistent changes to, the `grub.cfg` file. It enables, for example, changing GRUB menu entries to specify what arguments to pass to a kernel on system start and changing the default kernel.

In Red Hat Enterprise Linux 7, if `grubby` is invoked manually without specifying a GRUB configuration file, it defaults to searching for `/etc/grub2.cfg`, which is a symbolic link to the `grub.cfg` file, whose location is architecture dependent. If that file cannot be found it will search for an architecture dependent default.

#### Listing the Default Kernel

To find out the file name of the default kernel, enter a command as follows:

```bash
~]# grubby --default-kernel
/boot/vmlinuz-3.10.0-229.4.2.el7.x86_64
```

To find out the index number of the default kernel, enter a command as follows:

```bash
~]# grubby --default-index
0
```

#### Changing the Default Boot Entry

To make a persistent change in the kernel designated as the default kernel, use the `grubby` command as follows:
-]# grubby --set-default /boot/vmlinux-3.10.0-229.4.2.el7.x86_64

**Viewing the GRUB Menu Entry for a Kernel**

To list all the kernel menu entries, enter a command as follows:

-]$ grubby --info=ALL

On UEFI systems, all `grubby` commands must be entered as `root`.

To view the GRUB menu entry for a specific kernel, enter a command as follows:

-]$ grubby --info /boot/vmlinuz-3.10.0-229.4.2.el7.x86_64

```bash
index=0
kernel=/boot/vmlinuz-3.10.0-229.4.2.el7.x86_64
args="ro rd.lvm.lv=rhel/root crashkernel=auto rd.lvm.lv=rhel/swap
vconsole.font=latarcyrheb-sun16 vconsole.keymap=us rhgb quiet
LANG=en_US.UTF-8"
root=/dev/mapper/rhel-root
initrd=/boot/initramfs-3.10.0-229.4.2.el7.x86_64.img
title=Red Hat Enterprise Linux Server (3.10.0-229.4.2.el7.x86_64) 7.0 (Maipo)
```

Try tab completion to see the available kernels within the `/boot/` directory.

**Adding and Removing Arguments from a GRUB Menu Entry**

The `--update-kernel` option can be used to update a menu entry when used in combination with `--args` to add new arguments and `--remove-arguments` to remove existing arguments. These options accept a quoted space-separated list. The command to simultaneously add and remove arguments a from GRUB menu entry has the follow format:

```
grubby --remove-args="argX argY" --args="argA argB" --update-kernel /boot/kernel
```

To add and remove arguments from a kernel's GRUB menu entry, use a command as follows:

-]# grubby --remove-args="rhgb quiet" --args=console=ttyS0,115200 --update-kernel /boot/vmlinuz-3.10.0-229.4.2.el7.x86_64

This command removes the Red Hat graphical boot argument, enables boot message to be seen, and adds a serial console. As the console arguments will be added at the end of the line, the new console will take precedence over any other consoles configured.

To review the changes, use the `--info` command option as follows:

-]# grubby --info /boot/vmlinuz-3.10.0-229.4.2.el7.x86_64

```bash
index=0
kernel=/boot/vmlinuz-3.10.0-229.4.2.el7.x86_64
args="ro rd.lvm.lv=rhel/root crashkernel=auto rd.lvm.lv=rhel/swap
vconsole.font=latarcyrheb-sun16 vconsole.keymap=us LANG=en_US.UTF-8
ttyS0,115200"
root=/dev/mapper/rhel-root
initrd=/boot/initramfs-3.10.0-229.4.2.el7.x86_64.img
title=Red Hat Enterprise Linux Server (3.10.0-229.4.2.el7.x86_64) 7.0 (Maipo)
```
Updating All Kernel Menus with the Same Arguments
To add the same kernel boot arguments to all the kernel menu entries, enter a command as follows:

```bash
~# grubby --update-kernel=ALL --args=console=ttyS0,115200
```

The `--update-kernel` parameter also accepts DEFAULT or a comma separated list of kernel index numbers.

Changing a Kernel Argument
To change a value in an existing kernel argument, specify the argument again, changing the value as required. For example, to change the virtual console font size, use a command as follows:

```bash
~# grubby --args=vconsole.font=latarcyrheb-sun32 --update-kernel
/boot/vmlinux-3.10.0-229.4.2.el7.x86_64
index=0
kernel=/boot/vmlinux-3.10.0-229.4.2.el7.x86_64
args="ro rd.lvm.lv=rhel/root crashkernel=auto rd.lvm.lv=rhel/swap
vconsole.font=latarcyrheb-sun32 vconsole.keymap=us LANG=en_US.UTF-8"
root=/dev/mapper/rhel-root
initrd=/boot/initramfs-3.10.0-229.4.2.el7.x86_64.img
title=Red Hat Enterprise Linux Server (3.10.0-229.4.2.el7.x86_64) 7.0 (Maipo)
```

See the `grubby(8)` manual page for more command options.

25.5. CUSTOMIZING THE GRUB 2 CONFIGURATION FILE

GRUB 2 scripts search the user’s computer and build a boot menu based on what operating systems the scripts find. To reflect the latest system boot options, the boot menu is rebuilt automatically when the kernel is updated or a new kernel is added.

However, users may want to build a menu containing specific entries or to have the entries in a specific order. GRUB 2 allows basic customization of the boot menu to give users control of what actually appears on the screen.

GRUB 2 uses a series of scripts to build the menu; these are located in the `/etc/grub.d/` directory. The following files are included:

- `00_header`, which loads GRUB 2 settings from the `/etc/default/grub` file.
- `01_users`, which reads the superuser password from the `user.cfg` file. In Red Hat Enterprise Linux 7.0 and 7.1, this file was only created when boot password was defined in the kickstart file during installation, and it included the defined password in plain text.
- `10_linux`, which locates kernels in the default partition of Red Hat Enterprise Linux.
- `30_os-prober`, which builds entries for operating systems found on other partitions.
- `40_custom`, a template, which can be used to create additional menu entries.

Scripts from the `/etc/grub.d/` directory are read in alphabetical order and can be therefore renamed to change the boot order of specific menu entries.
IMPORTANT

With the GRUB_TIMEOUT key set to 0 in the /etc/default/grub file, GRUB 2 does not display the list of bootable kernels when the system starts up. In order to display this list when booting, press and hold any alphanumeric key when the BIOS information is displayed; GRUB 2 will present you with the GRUB menu.

25.5.1. Changing the Default Boot Entry

By default, the key for the GRUB_DEFAULT directive in the /etc/default/grub file is the word saved. This instructs GRUB 2 to load the kernel specified by the saved_entry directive in the GRUB 2 environment file, located at /boot/grub2/grubenv. You can set another GRUB record to be the default, using the grub2-set-default command, which will update the GRUB 2 environment file.

By default, the saved_entry value is set to the name of latest installed kernel of package type kernel. This is defined in /etc/sysconfig/kernel by the UPDATEDEFAULT and DEFAULTKERNEL directives. The file can be viewed by the root user as follows:

```
~
```
```
cat /etc/sysconfig/kernel
```

# UPDATEDEFAULT specifies if new-kernel-pkg should make
# new kernels the default
UPDATEDEFAULT=yes

# DEFAULTKERNEL specifies the default kernel package type
DEFAULTKERNEL=kernel
```

The DEFAULTKERNEL directive specifies what package type will be used as the default. Installing a package of type kernel-debug will not change the default kernel while the DEFAULTKERNEL is set to package type kernel.

GRUB 2 supports using a numeric value as the key for the saved_entry directive to change the default order in which the operating systems are loaded. To specify which operating system should be loaded first, pass its number to the grub2-set-default command. For example:

```
~
```
```
grub2-set-default 2
```

Note that the position of a menu entry in the list is denoted by a number starting with zero; therefore, in the example above, the third entry will be loaded. This value will be overwritten by the name of the next kernel to be installed.

To force a system to always use a particular menu entry, use the menu entry name as the key to the GRUB_DEFAULT directive in the /etc/default/grub file. To list the available menu entries, run the following command as root:

```
~
```
```
awk -F" \"" "$1=="menuentry " {print $2}" /etc/grub2.cfg
```

The file name /etc/grub2.cfg is a symbolic link to the grub.cfg file, whose location is architecture dependent. For reliability reasons, the symbolic link is not used in other examples in this chapter. It is better to use absolute paths when writing to a file, especially when repairing a system.

Changes to /etc/default/grub require rebuilding the grub.cfg file as follows:

```
- On BIOS-based machines, issue the following command as root:
```

```
- On System Administrator's Guide
544
```
25.5.2. Editing a Menu Entry

If required to prepare a new GRUB 2 file with different parameters, edit the values of the GRUB_CMDLINE_LINUX key in the /etc/default/grub file. Note that you can specify multiple parameters for the GRUB_CMDLINE_LINUX key, similarly to adding the parameters in the GRUB 2 boot menu. For example:

```
GRUB_CMDLINE_LINUX="console=tty0 console=ttyS0,9600n8"
```

Where `console=tty0` is the first virtual terminal and `console=ttyS0` is the serial terminal to be used.

Changes to /etc/default/grub require rebuilding the grub.cfg file as follows:

- On BIOS-based machines, issue the following command as root:
  ```
  ~# grub2-mkconfig -o /boot/grub2/grub.cfg
  ```
- On UEFI-based machines, issue the following command as root:
  ```
  ~# grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
  ```

25.5.3. Adding a new Entry

When executing the grub2-mkconfig command, GRUB 2 searches for Linux kernels and other operating systems based on the files located in the /etc/grub.d/ directory. The /etc/grub.d/10_linux script searches for installed Linux kernels on the same partition. The /etc/grub.d/30_os-prober script searches for other operating systems. Menu entries are also automatically added to the boot menu when updating the kernel.

The 40_custom file located in the /etc/grub.d/ directory is a template for custom entries and looks as follows:

```
#!/bin/sh
exec tail -n +3 $0
# This file provides an easy way to add custom menu entries. Simply type the
# menu entries you want to add after this comment. Be careful not to change
# the 'exec tail' line above.
```

This file can be edited or copied. Note that as a minimum, a valid menu entry must include at least the following:
25.5.4. Creating a Custom Menu

If you do not want menu entries to be updated automatically, you can create a custom menu.

**IMPORTANT**

Before proceeding, back up the contents of the `/etc/grub.d/` directory in case you need to revert the changes later.

**NOTE**

Note that modifying the `/etc/default/grub` file does not have any effect on creating custom menus.

1. On BIOS-based machines, copy the contents of `/boot/grub2/grub.cfg`, or, on UEFI machines, copy the contents of `/boot/efi/EFI/redhat/grub.cfg`. Put the content of the `grub.cfg` into the `/etc/grub.d/40_custom` file below the existing header lines. The executable part of the `40_custom` script has to be preserved.

2. From the content put into the `/etc/grub.d/40_custom` file, only the `menuentry` blocks are needed to create the custom menu. The `/boot/grub2/grub.cfg` and `/boot/efi/EFI/redhat/grub.cfg` files might contain function specifications and other content above and below the `menuentry` blocks. If you put these unnecessary lines into the `40_custom` file in the previous step, erase them.

This is an example of a custom `40_custom` script:

```bash
#!/bin/sh
echo 'First custom entry' --class red --class gnu-linux --class gnu --class os $menuentry_id_option 'gnulinux-3.10.0-67.el7.x86_64-advanced-32782dd0-4b47-4d56-a740-2076ab5e5976' {
    load_video
    set gfxpayload=keep
    insmod gzio
    insmod part_msdos
    insmod xfs
    set root='hd0,msdos1'
    if [ x$xfeature_platform_search_hint = xy ]; then
        search --no-floppy --fs-uuid --set=root --
hint='hd0,msdos1' 7885bba1-8aa7-4e5d-a7ad-821f4f52170a
    else
        search --no-floppy --fs-uuid --set=root 7885bba1-8aa7-
```
3. Remove all files from the `/etc/grub.d/` directory except the following:

- `00_header`,
- `40_custom`,
- `01_users` (if it exists),
- and `README`.

Alternatively, if you want to keep the files in the `/etc/grub2.d/` directory, make them unexecutable by running the `chmod a-x <file_name>` command.

4. Edit, add, or remove menu entries in the `40_custom` file as desired.

5. Rebuild the `grub.cfg` file by running the `grub2-mkconfig -o` command as follows:

   - On BIOS-based machines, issue the following command as `root`:
     ```bash
     ~$ grub2-mkconfig -o /boot/grub2/grub.cfg
     ```
   - On UEFI-based machines, issue the following command as `root`:
25.6. PROTECTING GRUB 2 WITH A PASSWORD

GRUB 2 offers two types of password protection:

- Password is required for modifying menu entries but not for booting existing menu entries;
- Password is required for modifying menu entries and for booting one, several, or all menu entries.

Configuring GRUB 2 to Require a Password only for Modifying Entries

To require password authentication for modifying GRUB 2 entries, follow these steps:

1. Run the `grub2-setpassword` command as root:

   ```sh
   ~]# grub2-setpassword
   ```

2. Enter and confirm the password:

   ```
   Enter password:
   Confirm password:
   ```

   Following this procedure creates a `/boot/grub2/user.cfg` file that contains the hash of the password. The user for this password, root, is defined in the `/boot/grub2/grub.cfg` file. With this change, modifying a boot entry during booting requires you to specify the root user name and your password.

Configuring GRUB 2 to Require a Password for Modifying and Booting Entries

Setting a password using the `grub2-setpassword` prevents menu entries from unauthorized modification but not from unauthorized booting. To also require password for booting an entry, follow these steps after setting the password with `grub2-setpassword`:

**WARNING**

If you forget your GRUB 2 password, you will not be able to boot the entries you reconfigure in the following procedure.

1. Open the `/boot/grub2/grub.cfg` file.

2. Find the boot entry that you want to protect with password by searching for lines beginning with `menuentry`.

3. Delete the `--unrestricted` parameter from the menu entry block, for example:

   ```
   [file contents truncated]
   menuentry 'Red Hat Enterprise Linux Server (3.10.0-327.18.2.rt56.223.e17_2.x86_64) 7.2 (Maipo)' --class red --class
   ```
"gnulinux --class gnu --class os --unrestricted $menuentry_id_option
'gnulinux-3.10.0-327.el7.x86_64-advanced-c109825c-de2f-4340-a0ef-4f47d19fe4bf' {
  load_video
  set gfxpayload=keep
[file contents truncated]

4. Save and close the file.

Now even booting the entry requires entering the root user name and password.

NOTE

Manual changes to the /boot/grub2/grub.cfg persist when new kernel versions are installed, but are lost when re-generating grub.cfg using the grub2-mkconfig command. Therefore, to retain password protection, use the above procedure after every use of grub2-mkconfig.

NOTE

If you delete the --unrestricted parameter from every menu entry in the /boot/grub2/grub.cfg file, all newly installed kernels will have menu entry created without --unrestricted and hence automatically inherit the password protection.

Passwords Set Before Updating to Red Hat Enterprise Linux 7.2

The grub2-setpassword tool was added in Red Hat Enterprise Linux 7.2 and is now the standard method of setting GRUB 2 passwords. This is in contrast to previous versions of Red Hat Enterprise Linux, where boot entries needed to be manually specified in the /etc/grub.d/40_custom file, and super users - in the /etc/grub.d/01_users file.

Additional GRUB 2 Users

Booting entries without the --unrestricted parameter requires the root password. However, GRUB 2 also enables creating additional non-root users that can boot such entries without providing a password. Modifying the entries still requires the root password. For information on creating such users, see the GRUB 2 Manual.

25.7. REINSTALLING GRUB 2

Reinstalling GRUB 2 is a convenient way to fix certain problems usually caused by an incorrect installation of GRUB 2, missing files, or a broken system. Other reasons to reinstall GRUB 2 include the following:

- Upgrading from the previous version of GRUB.
- The user requires the GRUB 2 boot loader to control installed operating systems. However, some operating systems are installed with their own boot loaders. Reinstalling GRUB 2 returns control to the desired operating system.
- Adding the boot information to another drive.

25.7.1. Reinstalling GRUB 2 on BIOS-Based Machines
When using the `grub2-install` command, the boot information is updated and missing files are restored. Note that the files are restored only if they are not corrupted.

Use the `grub2-install device` command to reinstall GRUB 2 if the system is operating normally. For example, if `sda` is your `device`:

```
~]# grub2-install /dev/sda
```

### 25.7.2. Reinstalling GRUB 2 on UEFI-Based Machines

When using the `yum reinstall grub2-efi shim` command, the boot information is updated and missing files are restored. Note that the files are restored only if they are not corrupted.

Use the `yum reinstall grub2-efi shim` command to reinstall GRUB 2 if the system is operating normally. For example:

```
~]# yum reinstall grub2-efi shim
```

### 25.7.3. Resetting and Reinstalling GRUB 2

This method completely removes all GRUB 2 configuration files and system settings. Apply this method to reset all configuration settings to their default values. Removing of the configuration files and subsequent reinstalling of GRUB 2 fixes failures caused by corrupted files and incorrect configuration. To do so, as `root`, follow these steps:

1. Run the `rm /etc/grub.d/*` command;
2. Run the `rm /etc/sysconfig/grub` command;
3. For EFI systems only, run the following command:
   ```
   ~]# yum reinstall grub2-efi shim grub2-tools
   ```
4. For BIOS and EFI systems, run this command:
   ```
   ~]# yum reinstall grub2-tools
   ```
5. Rebuild the `grub.cfg` file by running the `grub2-mkconfig -o` command as follows:
   - On BIOS-based machines, issue the following command as `root`:
     ```
     ~]# grub2-mkconfig -o /boot/grub2/grub.cfg
     ```
   - On UEFI-based machines, issue the following command as `root`:
     ```
     ~]# grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
     ```

### 25.8. UPGRADING FROM GRUB LEGACY TO GRUB 2
When you do an in-place upgrade of Red Hat Enterprise Linux (RHEL) from version 6 to 7, the upgrade from GRUB Legacy to GRUB 2 does not happen automatically, but it can be done manually. Perform the GRUB upgrade for these reasons:

- In RHEL 7 and later versions, GRUB Legacy is no longer maintained and does not receive updates.
- GRUB Legacy is unable to boot on systems without the /boot/ directory.
- GRUB 2 has more features and is more reliable.
- GRUB 2 supports more hardware configurations, file systems, and drive layouts.

**Prerequisites for upgrading**
Prior to upgrading your Red Hat Enterprise Linux 7 system, do a manual backup of GRUB Legacy. Note that GRUB Legacy is available through the grub package.

**Procedure 25.2. Creating a manual backup of GRUB Legacy**

1. Download the grub package:

   ```bash
   ~]# yum reinstall -y --downloadonly grub
   ```

2. Locate the downloaded package:

   ```bash
   ~]# find /var/cache/yum/ | grep "grub"
   ```

   **NOTE**
   If you did not change the default cache location of yum, then its cache is located in the /var/cache/yum/ directory. If you changed the default cache location of yum, consult its configuration to find it. For further information, see Working with Yum Cache and Configuring Yum and Yum Repositories.

3. Copy the package to a safe location, for example to the /root/ directory:

   ```bash
   ~]# cp /var/cache/yum/x86_64/6Server/rhel/packages/grub-0.97-99.el6.x86_64.rpm /root/
   ```

   **IMPORTANT**
   Do not copy the grub package into the /boot/ directory. This may cause the in-place upgrade from RHEL 6 to RHEL 7 to fail if /boot/ does not have enough free space. For more information, see the pre-upgrade and upgrade documentation:

   - Release Notes documentation
   - Knowledgebase Article
Upgrading from GRUB Legacy to GRUB 2 after the in-place upgrade of the operating system

Procedure 25.3. Upgrading from GRUB Legacy to GRUB 2

1. Install the grub package from its backup:

   ~]# rpm --install --force --nodeps grub-0.97-99.el6.x86_64.rpm

   This step ensures that you have a recovery option in case that the upgrade from GRUB Legacy to GRUB 2 fails at some point. Note that there can be various versions of the package, so you need to use the precise name of your backed up package.

2. Make sure that the grub2 package is installed. If grub2 is not on the system after the upgrade to RHEL 7, you can install it manually by running:

   ~]# yum install grub2

Determining bootable device file

1. Find out the GRUB Legacy designation for the bootable device. For that, view the GRUB Legacy configuration file /boot/grub/grub.conf and search for the root line:

   # grub.conf generated by anaconda
   #
   # Note that you do not have to rerun grub after making changes to
   # this file
   # NOTICE: You have a /boot partition. This means that
   # all kernel and initrd paths are relative to /boot/, eg.
   # root (hd0,0)
   # kernel /vmlinuz-version ro root=/dev/mapper/vg_rhel68-
   # lv_root
   # initrd /initrd-[generic-]version.img
   #boot=/dev/sda
   default=0
   timeout=5
   splashimage=(hd0,0)/grub/splash.xpm.gz
   hiddenmenu
   title Red Hat Enterprise Linux Server (2.6.32-642.4.2.el6.x86_64)
   root (hd0,0)
   kernel /vmlinuz-2.6.32-642.4.2.el6.x86_64 ro
   root=/dev/mapper/vg_rhel68-lv_root rd_NO_LUKS KEYBOARDTYPE=pc
   KEYTABLE=us LANG=en_US.UTF-8 rd_NO_MD SYSFONT=latarcyrheb-sun16
   crashkernel=auto rd_LVM_LV=vg_rhel68/lv_root
   rd_LVM_LV=vg_rhel68/lv_swap rd_NO_DM rhgb quiet
   initrd /initramfs-2.6.32-642.4.2.el6.x86_64.img
   title Red Hat Enterprise Linux 6 (2.6.32-642.el6.x86_64)
   root (hd0,0)
   kernel /vmlinuz-2.6.32-642.el6.x86_64 ro
   root=/dev/mapper/vg_rhel68-1v_root rd_NO_LUKS KEYBOARDTYPE=pc
   KEYTABLE=us LANG=en_US.UTF-8 rd_NO_MD SYSFONT=latarcyrheb-sun16
   crashkernel=auto rd_LVM_LV=vg_rhel68/lv_root
   rd_LVM_LV=vg_rhel68/lv_swap rd_NO_DM rhgb quiet
   initrd /initramfs-2.6.32-642.el6.x86_64.img
For each menu entry, the root line specifies the bootable device. In this example, hd0,0 is the bootable device.

2. Only perform this step if your /boot/grub/device.map is not correct. This might happen, for example, after changing hardware configuration.
   a. Recreate /boot/grub/device.map:
      ~]# grub-install --recheck /dev/sda
      The old configuration is backed up automatically in /boot/grub/device.map.backup.
   b. If the previous step broke your device mapping configuration, restore the backup:
      ~]# rm /boot/grub/device.map
      ~]# cp /boot/grub/device.map.backup /boot/grub/device.map

3. Determine the mapping of the GRUB Legacy device designation to the device file. For that, take the device found in step 1, and find the corresponding entry in the /boot/grub/device.map file:
   
   # this device map was generated by anaconda
   (hd0)  /dev/sda
   (hd1)  /dev/sdb

   In this example, the listing shows that for device hd0 the device file is /dev/sda.

   Make note of the device file, it will be used in the next procedure.

Generating the GRUB 2 configuration files
Now we will add GRUB 2 configuration without removing the original GRUB Legacy configuration. We will keep GRUB Legacy configuration in case GRUB 2 does not work correctly.

1. Install the GRUB 2 files to the /boot/grub/ directory of /dev/sdX disk:
   ~]# grub2-install --grub-setup=/bin/true /dev/sdX

   Substitute /dev/sdX with the bootable device file determined in the section called “Determining bootable device file”.

   The --grub-setup=/bin/true option ensures that the old GRUB Legacy configuration is not deleted.
WARNING

Note the difference in the configuration file extensions:

- .conf is for GRUB
- .cfg is for GRUB 2

Do not overwrite the old GRUB configuration file by mistake in the next step.

2. Generate the /boot/grub2/grub.cfg:

   ~]# grub2-mkconfig -o /boot/grub2/grub.cfg

NOTE

For customizing the generated GRUB 2 configuration file, see Section 25.5, “Customizing the GRUB 2 Configuration File”. You should make changes in /etc/default/grub, not directly in /boot/grub2/grub.cfg. Otherwise, changes in /boot/grub2/grub.cfg are lost every time the file is re-generated.

Testing GRUB 2 with GRUB still installed

Now we will test GRUB 2 without removing the GRUB Legacy configuration. The GRUB Legacy configuration needs to stay until GRUB 2 configuration is verified; otherwise the system might become unbootable. To safely test GRUB 2 configuration, we will start GRUB 2 from GRUB Legacy.

1. Add a new section into /boot/grub/grub.conf:

   
   title GRUB 2 Test
   root (hd0,0)
   kernel /grub2/i386-pc/core.img
   boot

   Substitute (hd0,0) with the GRUB Legacy bootable device designation.

2. Reboot the system.

3. When presented with a GRUB Legacy menu, select the GRUB 2 Test entry.

4. When presented with a GRUB 2 menu, select a kernel to boot.

5. If the above did not work, restart, and do not choose the GRUB 2 Test entry on next boot.

Replacing and removing GRUB Legacy

If GRUB 2 worked successfully, replace GRUB Legacy and remove it from the system:

1. Overwrite the GRUB Legacy boot sector with the GRUB 2 bootloader:
~]# grub2-install /dev/sda

2. Uninstall the grub packages:

~]# yum remove grub

The upgrade to GRUB 2 is now finished.

### 25.9. GRUB 2 OVER A SERIAL CONSOLE

If you use computers with no display or keyboard, it can be very useful to control the machines through serial communications.

#### 25.9.1. Configuring the GRUB 2 Menu

To set the system to use a serial terminal only during a single boot process, when the GRUB 2 boot menu appears, move the cursor to the kernel you want to start, and press the `e` key to edit the kernel parameters. Remove the `rhgb` and `quiet` parameters and add console parameters at the end of the `linux16` line as follows:

```
linux16 /vmlinuz-3.10.0-0.rc4.59.el7.x86_64 root=/dev/mapper/rhel-root ro rd.md=0 rd.dm=0 rd.lvm.lv=rhel/swap crashkernel=auto rd.luks=0 vconsole.keymap=us rd.lvm.lv=rhel/root console=ttyS0,115200
```

These settings are not persistent and apply only for a single boot.

To make persistent changes to a menu entry on a system, use the `grubby` tool. For example, to update the entry for the default kernel, enter a command as follows:

```
~]# grubby --remove-args="rhgb quiet" --args=console=ttyS0,115200 --update-kernel=DEFAULT
```

The `--update-kernel` parameter also accepts the keyword `ALL` or a comma separated list of kernel index numbers. See the section called “Adding and Removing Arguments from a GRUB Menu Entry” for more information on using `grubby`.

If required to build a new GRUB 2 configuration file, add the following two lines in the `/etc/default/grub` file:

```
GRUB_TERMINAL="serial"
GRUB_SERIAL_COMMAND="serial --speed=9600 --unit=0 --word=8 --parity=no --stop=1"
```

The first line disables the graphical terminal. Note that specifying the `GRUB_TERMINAL` key overrides values of `GRUB_TERMINAL_INPUT` and `GRUB_TERMINAL_OUTPUT`. On the second line, adjust the baud rate, parity, and other values to fit your environment and hardware. A much higher baud rate, for example 115200, is preferable for tasks such as following log files. Once you have completed the changes in the `/etc/default/grub` file, it is necessary to update the GRUB 2 configuration file.

Rebuild the `grub.cfg` file by running the `grub2-mkconfig -o` command as follows:
On BIOS-based machines, issue the following command as root:

```
~# grub2-mkconfig -o /boot/grub2/grub.cfg
```

On UEFI-based machines, issue the following command as root:

```
~# grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
```

**NOTE**

In order to access the GRUB terminal over a serial connection an additional option must be added to a kernel definition to make that particular kernel monitor a serial connection. For example:

```
console=ttyS0,9600n8
```

Where `console=ttyS0` is the serial terminal to be used, `9600` is the baud rate, `n` is for no parity, and `8` is the word length in bits. A much higher baud rate, for example `115200`, is preferable for tasks such as following log files.

For more information on serial console settings, see the section called "Installable and External Documentation".

### 25.9.2. Using screen to Connect to the Serial Console

The `screen` tool serves as a capable serial terminal. To install it, run as root:

```
~# yum install screen
```

To connect to your machine using the serial console, use a command in the follow format:

```
screen /dev/console_port baud_rate
```

By default, if no option is specified, `screen` uses the standard 9600 baud rate. To set a higher baud rate, enter:

```
~$ screen /dev/console_port 115200
```

Where `console_port` is `ttyS0`, or `ttyUSB0`, and so on.

To end the session in `screen`, press `Ctrl+a`, type `:quit` and press `Enter`.

See the `screen(1)` manual page for additional options and detailed information.

### 25.10. TERMINAL MENU EDITING DURING BOOT

Menu entries can be modified and arguments passed to the kernel on boot. This is done using the menu entry editor interface, which is triggered when pressing the `e` key on a selected menu entry in the boot loader menu. The `Esc` key discards any changes and reloads the standard menu interface. The `c` key loads the command line interface.

The command line interface is the most basic GRUB interface, but it is also the one that grants the
most control. The command line makes it possible to type any relevant GRUB commands followed by
the Enter key to execute them. This interface features some advanced features similar to shell,
including Tab key completion based on context, and Ctrl+a to move to the beginning of a line and
Ctrl+e to move to the end of a line. In addition, the arrow, Home, End, and Delete keys work as they
do in the bash shell.

25.10.1. Booting to Rescue Mode

Rescue mode provides a convenient single-user environment and allows you to repair your system in
situations when it is unable to complete a normal booting process. In rescue mode, the system
attempts to mount all local file systems and start some important system services, but it does not
activate network interfaces or allow more users to be logged into the system at the same time. In
Red Hat Enterprise Linux 7, rescue mode is equivalent to single user mode and requires the root
password.

1. To enter rescue mode during boot, on the GRUB 2 boot screen, press the e key for edit.

2. Add the following parameter at the end of the linux line on 64-Bit IBM Power Series, the
linux16 line on x86-64 BIOS-based systems, or the linuxefi line on UEFI systems:

\[ \text{systemd.unit=rescue.target} \]

Press Ctrl+a and Ctrl+e to jump to the start and end of the line, respectively. On some
systems, Home and End might also work.

Note that equivalent parameters, 1, s, and single, can be passed to the kernel as well.

3. Press Ctrl+x to boot the system with the parameter.

25.10.2. Booting to Emergency Mode

Emergency mode provides the most minimal environment possible and allows you to repair your
system even in situations when the system is unable to enter rescue mode. In emergency mode, the
system mounts the root file system only for reading, does not attempt to mount any other local file
systems, does not activate network interfaces, and only starts few essential services. In Red Hat
Enterprise Linux 7, emergency mode requires the root password.

1. To enter emergency mode, on the GRUB 2 boot screen, press the e key for edit.

2. Add the following parameter at the end of the linux line on 64-Bit IBM Power Series, the
linux16 line on x86-64 BIOS-based systems, or the linuxefi line on UEFI systems:

\[ \text{systemd.unit=emergency.target} \]

Press Ctrl+a and Ctrl+e to jump to the start and end of the line, respectively. On some
systems, Home and End might also work.

Note that equivalent parameters, emergency and -b, can be passed to the kernel as well.

3. Press Ctrl+x to boot the system with the parameter.

25.10.3. Booting to the Debug Shell
The systemd debug shell provides a shell very early in the startup process that can be used to diagnose systemd related boot-up problems. Once in the debug shell, systemctl commands such as systemctl list-jobs, and systemctl list-units can be used to look for the cause of boot problems. In addition, the debug option can be added to the kernel command line to increase the number of log messages. For systemd, the kernel command-line option debug is now a shortcut for systemd.log_level=debug.

Procedure 25.4. Adding the Debug Shell Command

To activate the debug shell only for this session, proceed as follows:

1. On the GRUB 2 boot screen, move the cursor to the menu entry you want to edit and press the e key for edit.

2. Add the following parameter at the end of the linux line on 64-Bit IBM Power Series, the linux16 line on x86-64 BIOS-based systems, or the linuxefi line on UEFI systems:

   systemctl.debug-shell

   Optionally add the debug option.

   Press Ctrl+a and Ctrl+e to jump to the start and end of the line, respectively. On some systems, Home and End might also work.

3. Press Ctrl+x to boot the system with the parameter.

If required, the debug shell can be set to start on every boot by enabling it with the systemctl enable debug-shell command. Alternatively, the grubby tool can be used to make persistent changes to the kernel command line in the GRUB 2 menu. See Section 25.4, “Making Persistent Changes to a GRUB 2 Menu Using the grubby Tool” for more information on using grubby.

WARNING

Permanently enabling the debug shell is a security risk because no authentication is required to use it. Disable it when the debugging session has ended.

Procedure 25.5. Connecting to the Debug Shell

During the boot process, the systemd-debug-generator will configure the debug shell on TTY9.

1. Press Ctrl+Alt+F9 to connect to the debug shell. If working with a virtual machine, sending this key combination requires support from the virtualization application. For example, if using Virtual Machine Manager, select Send Key → Ctrl+Alt+F9 from the menu.

2. The debug shell does not require authentication, therefore a prompt similar to the following should be seen on TTY9: [root@localhost /]#

3. If required, to verify you are in the debug shell, enter a command as follows:

   [root@localhost /]# systemctl status $$
To diagnose start up problems, certain systemd units can be masked by adding
systemd.mask=unit_name one or more times on the kernel command line. To start additional
processes during the boot process, add systemd.wants=unit_name to the kernel command line. The
systemd-debug-generator(8) manual page describes these options.

25.10.4. Changing and Resetting the Root Password

Setting up the root password is a mandatory part of the Red Hat Enterprise Linux 7 installation. If you
forget or lose the root password it is possible to reset it, however users who are members of the
wheel group can change the root password as follows:

```bash
$ sudo passwd root
```

Note that in GRUB 2, resetting the password is no longer performed in single-user mode as it was in
GRUB included in Red Hat Enterprise Linux 6. The root password is now required to operate in
single-user mode as well as in emergency mode.

Two procedures for resetting the root password are shown here:

- **Procedure 25.6, “Resetting the Root Password Using an Installation Disk”** takes you to a shell
  prompt, without having to edit the GRUB menu. It is the shorter of the two procedures and it is
  also the recommended method. You can use a boot disk or a normal Red Hat Enterprise Linux 7
  installation disk.

- **Procedure 25.7, “Resetting the Root Password Using rd.break”** makes use of rd.break to
  interrupt the boot process before control is passed from initramfs to systemd. The
  disadvantage of this method is that it requires more steps, includes having to edit the GRUB
  menu, and involves choosing between a possibly time consuming SELinux file relabel or
  changing the SELinux enforcing mode and then restoring the SELinux security context for
  /etc/shadow/ when the boot completes.

**Procedure 25.6. Resetting the Root Password Using an Installation Disk**

1. Start the system and when BIOS information is displayed, select the option for a boot menu
   and select to boot from the installation disk.

2. Choose Troubleshooting.

3. Choose Rescue a Red Hat Enterprise Linux System.
4. Choose **Continue** which is the default option. At this point you will be promoted for a passphrase if an encrypted file system is found.

5. Press **OK** to acknowledge the information displayed until the shell prompt appears.

6. Change the file system **root** as follows:

   ```bash
   sh-4.2# chroot /mnt/sysimage
   ```

7. Enter the **passwd** command and follow the instructions displayed on the command line to change the **root** password.

8. Remove the **autorelabel** file to prevent a time consuming SELinux relabel of the disk:

   ```bash
   sh-4.2# rm -f /.autorelabel
   ```

9. Enter the **exit** command to exit the **chroot** environment.

10. Enter the **exit** command again to resume the initialization and finish the system boot.

**Procedure 25.7. Resetting the Root Password Using rd.break**

1. Start the system and, on the GRUB 2 boot screen, press the **e** key for edit.

2. Remove the **rhgb** and **quiet** parameters from the end, or near the end, of the **linux16** line, or **linuxefi** on UEFI systems.

   Press **Ctrl+a** and **Ctrl+e** to jump to the start and end of the line, respectively. On some systems, **Home** and **End** might also work.

   **IMPORTANT**

   The **rhgb** and **quiet** parameters must be removed in order to enable system messages.

3. Add the following parameters at the end of the **linux** line on 64-Bit IBM Power Series, the **linux16** line on x86-64 BIOS-based systems, or the **linuxefi** line on UEFI systems:

   ```bash
   rd.break enforcing=0
   ```

   Adding the **enforcing=0** option enables omitting the time consuming SELinux relabeling process.

   The **initramfs** will stop before passing control to the Linux kernel, enabling you to work with the **root** file system.

   Note that the **initramfs** prompt will appear on the last console specified on the Linux line.

4. Press **Ctrl+x** to boot the system with the changed parameters.

   With an encrypted file system, a password is required at this point. However the password prompt might not appear as it is obscured by logging messages. You can press the **Backspace** key to see the prompt. Release the key and enter the password for the encrypted file system,
while ignoring the logging messages.

The `initramfs switch_root` prompt appears.

5. The file system is mounted read-only on `/sysroot/`. You will not be allowed to change the password if the file system is not writable.

Remount the file system as writable:

```
switch_root:/# mount -o remount,rw /sysroot
```

6. The file system is remounted with write enabled.

Change the file system's root as follows:

```
switch_root:/# chroot /sysroot
```

The prompt changes to `sh-4.2#`.

7. Enter the `passwd` command and follow the instructions displayed on the command line to change the root password.

Note that if the system is not writable, the `passwd` tool fails with the following error:

```
Authentication token manipulation error
```

8. Updating the password file results in a file with the incorrect SELinux security context. To relabel all files on next system boot, enter the following command:

```
sh-4.2# touch /auto.relabel
```

Alternatively, to save the time it takes to relabel a large disk, you can omit this step provided you included the `enforcing=0` option in step 3.

9. Remount the file system as read only:

```
sh-4.2# mount -o remount,ro /
```

10. Enter the `exit` command to exit the `chroot` environment.

11. Enter the `exit` command again to resume the initialization and finish the system boot.

With an encrypted file system, a password or phrase is required at this point. However the password prompt might not appear as it is obscured by logging messages. You can press and hold the Backspace key to see the prompt. Release the key and enter the password for the encrypted file system, while ignoring the logging messages.

```
NOTE
```

Note that the SELinux relabeling process can take a long time. A system reboot will occur automatically when the process is complete.
12. If you added the enforcing=0 option in step 3 and omitted the `touch /etc/autorelabel` command in step 8, enter the following command to restore the `/etc/shadow` file's SELinux security context:

```
~# restorecon /etc/shadow
```

Enter the following commands to turn SELinux policy enforcement back on and verify that it is on:

```
~# setenforce 1
~# getenforce
Enforcing
```

25.11. UNIFIED EXTENSIBLE FIRMWARE INTERFACE (UEFI) SECURE BOOT

The Unified Extensible Firmware Interface (UEFI) Secure Boot technology ensures that the system firmware checks whether the system boot loader is signed with a cryptographic key authorized by a database of public keys contained in the firmware. With signature verification in the next-stage boot loader and kernel, it is possible to prevent the execution of kernel space code which has not been signed by a trusted key.

A chain of trust is established from the firmware to the signed drivers and kernel modules as follows. The first-stage boot loader, `shim.efi`, is signed by a UEFI private key and authenticated by a public key, signed by a certificate authority (CA), stored in the firmware database. The `shim.efi` contains the Red Hat public key, “Red Hat Secure Boot (CA key 1)”, which is used to authenticate both the GRUB 2 boot loader, `grubx64.efi`, and the Red Hat kernel. The kernel in turn contains public keys to authenticate drivers and modules.

Secure Boot is the boot path validation component of the Unified Extensible Firmware Interface (UEFI) specification. The specification defines:

- a programming interface for cryptographically protected UEFI variables in non-volatile storage,
- how the trusted X.509 root certificates are stored in UEFI variables,
- validation of UEFI applications like boot loaders and drivers,
- procedures to revoke known-bad certificates and application hashes.

UEFI Secure Boot does not prevent the installation or removal of second-stage boot loaders, nor require explicit user confirmation of such changes. Signatures are verified during booting, not when the boot loader is installed or updated. Therefore, UEFI Secure Boot does not stop boot path manipulations, it helps in the detection of unauthorized changes. A new boot loader or kernel will work as long as it is signed by a key trusted by the system.

25.11.1. UEFI Secure Boot Support in Red Hat Enterprise Linux 7

Red Hat Enterprise Linux 7 includes support for the UEFI Secure Boot feature, which means that Red Hat Enterprise Linux 7 can be installed and run on systems where UEFI Secure Boot is enabled. On UEFI-based systems with the Secure Boot technology enabled, all drivers that are loaded must be
signed with a trusted key, otherwise the system will not accept them. All drivers provided by Red Hat are signed by one of Red Hat's private keys and authenticated by the corresponding Red Hat public key in the kernel.

If you want to load externally built drivers, drivers that are not provided on the Red Hat Enterprise Linux DVD, you must make sure these drivers are signed as well.

Information on signing custom drivers is available in Section 27.8, “Signing Kernel Modules for Secure Boot”.

Restrictions Imposed by UEFI Secure Boot
As UEFI Secure Boot support in Red Hat Enterprise Linux 7 is designed to ensure that the system only runs kernel mode code after its signature has been properly authenticated, certain restrictions exist.

GRUB 2 module loading is disabled as there is no infrastructure for signing and verification of GRUB 2 modules, which means allowing them to be loaded would constitute execution of untrusted code inside the security perimeter that Secure Boot defines. Instead, Red Hat provides a signed GRUB 2 binary that has all the modules supported on Red Hat Enterprise Linux 7 already included.

More detailed information is available in the Red Hat Knowledgebase article Restrictions Imposed by UEFI Secure Boot.

25.12. ADDITIONAL RESOURCES
Please see the following resources for more information on the GRUB 2 boot loader:

Installed Documentation

- /usr/share/doc/grub2-tools-version-number/ – This directory contains information about using and configuring GRUB 2. version-number corresponds to the version of the GRUB 2 package installed.

- info grub2 – The GRUB 2 info page contains a tutorial, a user reference manual, a programmer reference manual, and a FAQ document about GRUB 2 and its usage.

- grubby(8) – The manual page for the command-line tool for configuring GRUB and GRUB 2.

- new-kernel-pkg(8) – The manual page for the tool to script kernel installation.

Installable and External Documentation

- /usr/share/doc/kernel-doc-kernel_version/Documentation/serial-console.txt – This file, which is provided by the kernel-doc package, contains information on the serial console. Before accessing the kernel documentation, you must run the following command as root:

  ```bash
  ~ ] # yum install kernel-doc
  ```

- Red Hat Installation Guide – The Installation Guide provides basic information on GRUB 2, for example, installation, terminology, interfaces, and commands.
CHAPTER 26. MANUALLY UPGRADING THE KERNEL

The Red Hat Enterprise Linux kernel is custom-built by the Red Hat Enterprise Linux kernel team to ensure its integrity and compatibility with supported hardware. Before Red Hat releases a kernel, it must first pass a rigorous set of quality assurance tests.

Red Hat Enterprise Linux kernels are packaged in the RPM format so that they are easy to upgrade and verify using the Yum or PackageKit package managers. PackageKit automatically queries the Red Hat Content Delivery Network servers and informs you of packages with available updates, including kernel packages.

This chapter is therefore only useful for users who need to manually update a kernel package using the rpm command instead of yum.

WARNING
Whenever possible, use either the Yum or PackageKit package manager to install a new kernel because they always install a new kernel instead of replacing the current one, which could potentially leave your system unable to boot.

WARNING
Building a custom kernel is not supported by the Red Hat Global Services Support team, and therefore is not explored in this manual.

For more information on installing kernel packages with yum, see Section 8.1.2, “Updating Packages”. For information on Red Hat Content Delivery Network, see Chapter 6, Registering the System and Managing Subscriptions.

26.1. OVERVIEW OF KERNEL PACKAGES

Red Hat Enterprise Linux contains the following kernel packages:

- kernel — Contains the kernel for single-core, multi-core, and multi-processor systems.
- kernel-debug — Contains a kernel with numerous debugging options enabled for kernel diagnosis, at the expense of reduced performance.
- kernel-devel — Contains the kernel headers and makefiles sufficient to build modules against the kernel package.
- kernel-debug-devel — Contains the development version of the kernel with numerous debugging options enabled for kernel diagnosis, at the expense of reduced performance.
- kernel-doc — Documentation files from the kernel source. Various portions of the Linux kernel
and the device drivers shipped with it are documented in these files. Installation of this package provides a reference to the options that can be passed to Linux kernel modules at load time.

By default, these files are placed in the `/usr/share/doc/kernel-doc-<kernel_version>/` directory.

- kernel-headers – Includes the C header files that specify the interface between the Linux kernel and user-space libraries and programs. The header files define structures and constants that are needed for building most standard programs.

- linux-firmware – Contains all of the firmware files that are required by various devices to operate.

- perf – This package contains the `perf` tool, which enables performance monitoring of the Linux kernel.

- kernel-abi-whitelists – Contains information pertaining to the Red Hat Enterprise Linux kernel ABI, including a lists of kernel symbols that are needed by external Linux kernel modules and a yum plug-in to aid enforcement.

- kernel-tools – Contains tools for manipulating the Linux kernel and supporting documentation.

## 26.2. PREPARING TO UPGRADE

Before upgrading the kernel, it is recommended that you take some precautionary steps.

First, ensure that working boot media exists for the system in case a problem occurs. If the boot loader is not configured properly to boot the new kernel, you can use this media to boot into Red Hat Enterprise Linux.

USB media often comes in the form of flash devices sometimes called pen drives, thumb disks, or keys, or as an externally-connected hard disk device. Almost all media of this type is formatted as a VFAT file system. You can create bootable USB media on media formatted as ext2, ext3, ext4, or VFAT.

You can transfer a distribution image file or a minimal boot media image file to USB media. Make sure that sufficient free space is available on the device. Around 4 GB is required for a distribution DVD image, around 700 MB for a distribution CD image, or around 10 MB for a minimal boot media image.

You must have a copy of the `boot.iso` file from a Red Hat Enterprise Linux installation DVD, or installation CD-ROM #1, and you need a USB storage device formatted with the VFAT file system and around 16 MB of free space. The following procedure will not affect existing files on the USB storage device unless they have the same path names as the files that you copy onto it. To create USB boot media, perform the following commands as the root user:

1. Install the `syslinux` package if it is not installed on your system. To do so, as root, run the `yum install syslinux` command.

2. Install the `SYSLINUX` bootloader on the USB storage device:

   ```
   ~]# syslinux /dev/sdX1
   ```

   ...where sdX is the device name.

3. Create mount points for `boot.iso` and the USB storage device:
# mkdir /mnt/isoboot /mnt/diskboot

4. Mount `boot.iso`:
   ```
   ~
   ~
   ~
   ~
   ~
   ~
   ~
   ```

5. Mount the USB storage device:
   ```
   ~
   ~
   ~
   ~
   ~
   ~
   ~
   ```

6. Copy the ISOLINUX files from the `boot.iso` to the USB storage device:
   ```
   ~
   ~
   ~
   ~
   ~
   ~
   ~
   ```

7. Use the `isolinux.cfg` file from `boot.iso` as the `syslinux.cfg` file for the USB device:
   ```
   ~
   ~
   ~
   ~
   ~
   ~
   ~
   ```

8. Unmount `boot.iso` and the USB storage device:
   ```
   ~
   ~
   ~
   ~
   ~
   ~
   ~
   ```

9. You should reboot the machine with the boot media and verify that you are able to boot with it before continuing.

Alternatively, on systems with a floppy drive, you can create a boot diskette by installing the `mkbootdisk` package and running the `mkbootdisk` command as `root`. See `man mkbootdisk` man page after installing the package for usage information.

To determine which kernel packages are installed, execute the command `yum list installed "kernel-**"` at a shell prompt. The output will comprise some or all of the following packages, depending on the system's architecture, and the version numbers might differ:

   ```
   ~
   ```

From the output, determine which packages need to be downloaded for the kernel upgrade. For a single processor system, the only required package is the kernel package. See Section 26.1, "Overview of Kernel Packages" for descriptions of the different packages.

## 26.3. DOWNLOADING THE UPGRADED KERNEL

There are several ways to determine if an updated kernel is available for the system:

- Security Errata – See [https://access.redhat.com/site/security/updates/active/](https://access.redhat.com/site/security/updates/active/) for information on security errata, including kernel upgrades that fix security issues.

- The Red Hat Content Delivery Network – For a system subscribed to the Red Hat Content Delivery Network, the `yum` package manager can download the latest kernel and upgrade the
kernel on the system. The Dracut utility will create an initial RAM disk image if needed, and configure the boot loader to boot the new kernel. For more information on installing packages from the Red Hat Content Delivery Network, see Chapter 8, Yum. For more information on subscribing a system to the Red Hat Content Delivery Network, see Chapter 6, Registering the System and Managing Subscriptions.

If yum was used to download and install the updated kernel from the Red Hat Network, follow the instructions in Section 26.5, “Verifying the Initial RAM Disk Image” and Section 26.6, “Verifying the Boot Loader” only, do not change the kernel to boot by default. Red Hat Network automatically changes the default kernel to the latest version. To install the kernel manually, continue to Section 26.4, “Performing the Upgrade”.

### 26.4. PERFORMING THE UPGRADE

After retrieving all of the necessary packages, it is time to upgrade the existing kernel.

**IMPORTANT**

It is strongly recommended that you keep the old kernel in case there are problems with the new kernel.

At a shell prompt, change to the directory that contains the kernel RPM packages. Use the `-i` argument with the `rpm` command to keep the old kernel. Do not use the `-U` option, since it overwrites the currently installed kernel, which creates boot loader problems. For example:

```bash
~# rpm -ivh kernel-kernel_version.arch.rpm
```

The next step is to verify that the initial RAM disk image has been created. See Section 26.5, “Verifying the Initial RAM Disk Image” for details.

### 26.5. VERIFYING THE INITIAL RAM DISK IMAGE

The job of the initial RAM disk image is to preload the block device modules, such as for IDE, SCSI or RAID, so that the root file system, on which those modules normally reside, can then be accessed and mounted. On Red Hat Enterprise Linux 7 systems, whenever a new kernel is installed using either the Yum, PackageKit, or RPM package manager, the Dracut utility is always called by the installation scripts to create an initramfs (initial RAM disk image).

If you make changes to the kernel attributes by modifying the `/etc/sysctl.conf` file or another sysctl configuration file, and if the changed settings are used early in the boot process, then rebuilding the Initial RAM Disk Image by running the `dracut -f` command might be necessary. An example is if you have made changes related to networking and are booting from network-attached storage.

On all architectures other than IBM eServer System i (see the section called “Verifying the Initial RAM Disk Image and Kernel on IBM eServer System i”), you can create an initramfs by running the `dracut` command. However, you usually don't need to create an initramfs manually: this step is automatically performed if the kernel and its associated packages are installed or upgraded from RPM packages distributed by Red Hat.

You can verify that an initramfs corresponding to your current kernel version exists and is specified correctly in the `grub.cfg` configuration file by following this procedure:
Procedure 26.1. Verifying the Initial RAM Disk Image

1. As root, list the contents in the /boot directory and find the kernel (vmlinuz-kernel_version) and initramfs-kernel_version with the latest (most recent) version number:

Example 26.1. Ensuring that the kernel and initramfs versions match

~]$ ls /boot
config-3.10.0-67.el7.x86_64
config-3.10.0-78.el7.x86_64
efi
grub
grub2
initramfs-0-rescue-07f43f20a54c4ce8ada8b70d33fd001c.img
initramfs-3.10.0-67.el7.x86_64.img
initramfs-3.10.0-78.el7.x86_64.img
initramfs-3.10.0-78.el7.x86_64kdump.img
initrd-plymouth.img
symvers-3.10.0-67.el7.x86_64.gz
symvers-3.10.0-78.el7.x86_64.gz
System.map-3.10.0-67.el7.x86_64
System.map-3.10.0-78.el7.x86_64
vmlinuz-0-rescue-07f43f20a54c4ce8ada8b70d33fd001c
vmlinuz-3.10.0-67.el7.x86_64
vmlinuz-3.10.0-78.el7.x86_64

Example 26.1, “Ensuring that the kernel and initramfs versions match” shows that:

- we have three kernels installed (or, more correctly, three kernel files are present in the /boot directory),
- the latest kernel is vmlinuz-3.10.0-78.el7.x86_64, and
- an initramfs file matching our kernel version, initramfs-3.10.0-78.el7.x86_64kdump.img, also exists.

IMPORTANT

In the /boot directory you might find several initramfs-kernel_versionkdump.img files. These are special files created by the Kdump mechanism for kernel debugging purposes, are not used to boot the system, and can safely be ignored. For more information on kdump, see the Red Hat Enterprise Linux 7 Kernel Crash Dump Guide.

2. If your initramfs-kernel_version file does not match the version of the latest kernel in the /boot directory, or, in certain other situations, you might need to generate an initramfs file with the Dracut utility. Simply invoking dracut as root without options causes it to generate an initramfs file in /boot for the latest kernel present in that directory:

~]$ dracut
You must use the \texttt{-f, --force} option if you want \texttt{dracut} to overwrite an existing \texttt{initramfs} (for example, if your \texttt{initramfs} has become corrupt). Otherwise \texttt{dracut} will refuse to overwrite the existing \texttt{initramfs} file:

\verbatim
~\] # dracut
Will not override existing initramfs (/boot/initramfs-3.10.0-78.el7.x86_64.img) without --force
\endverbatim

You can create an initramfs in the current directory by calling \texttt{dracut} \texttt{initramfs\_name kernel\_version}:

\verbatim
~\] # dracut "initramfs-$(uname -r).img" $(uname -r)
\endverbatim

If you need to specify specific kernel modules to be preloaded, add the names of those modules (minus any file name suffixes such as .ko) inside the parentheses of the \texttt{add\_dracutmodules+="module [more\_modules]"} directive of the \texttt{/etc/dracut.conf} configuration file. You can list the file contents of an \texttt{initramfs} image file created by \texttt{dracut} by using the \texttt{lsinitrd} \texttt{initramfs\_file} command:

\verbatim
~\] # lsinitrd /boot/initramfs-3.10.0-78.el7.x86_64.img
Image: /boot/initramfs-3.10.0-78.el7.x86_64.img: 11M
====================================================================
====
   drwxr-xr-x  12 root     root            0 Feb  5 06:35 .
   drwxr-xr-x   2 root     root            0 Feb  5 06:35 proc
  lrwxrwxrwx   1 root     root           24 Feb  5 06:35 init ->
/usr/lib/systemd/systemd
   drwxr-xr-x   2 root     root            0 Feb  5 06:35 etc
   drwxr-xr-x   2 root     root            0 Feb  5 06:35
/usr/lib/modprobe.d
[output truncated]
\endverbatim

See \texttt{man dracut} and \texttt{man dracut.conf} for more information on options and usage.

3. Examine the \texttt{/boot/grub2/grub.cfg} configuration file to ensure that an \texttt{initramfs\_kernel\_version.img} file exists for the kernel version you are booting. For example:

\verbatim
~\] # grep initramfs /boot/grub2/grub.cfg
initrd16 /initramfs-3.10.0-123.el7.x86_64.img
initrd16 /initramfs-0-rescue-6d547dbfd01c46f6a4c1baa8c4743f57.img
\endverbatim

See Section 26.6, “Verifying the Boot Loader” for more information.

\textbf{Verifying the Initial RAM Disk Image and Kernel on IBM eServer System i}

On IBM eServer System i machines, the initial RAM disk and kernel files are combined into a single file, which is created with the \texttt{add\_Ram\_Disk} command. This step is performed automatically if the kernel and its associated packages are installed or upgraded from the RPM packages distributed by Red Hat; thus, it does not need to be executed manually. To verify that it was created, run the following command as root to make sure the \texttt{/boot/vmlinitrd\_kernel\_version} file already exists:
ls -l /boot/

The *kernel_version* should match the version of the kernel just installed.

**Reversing the Changes Made to the Initial RAM Disk Image**

In some cases, for example, if you misconfigure the system and it no longer boots, you may need to reverse the changes made to the Initial RAM Disk Image by following this procedure:

**Procedure 26.2. Reversing Changes Made to the Initial RAM Disk Image**

1. Reboot the system choosing the rescue kernel in the GRUB menu.

2. Change the incorrect setting that caused the **initramfs** to malfunction.

3. Recreate the **initramfs** with the correct settings by running the following command as root:

   ```
   ~
   dracut --kver kernel_version --force
   ```

The above procedure might be useful if, for example, you incorrectly set the `vm.nr_hugepages` in the `sysctl.conf` file. Because the `sysctl.conf` file is included in **initramfs**, the new `vm.nr_hugepages` setting gets applied in **initramfs** and causes rebuilding of the **initramfs**. However, because the setting is incorrect, the new **initramfs** is broken and the newly built kernel does not boot, which necessitates correcting the setting using the above procedure.

**Listing the Contents of the Initial RAM Disk Image**

To list the files that are included in the **initramfs**, run the following command as root:

```
~
lsinitrd
```

To only list files in the `/etc` directory, use the following command:

```
~
lsinitrd | grep etc/
```

To output the contents of a specific file stored in the **initramfs** for the current kernel, use the `-f` option:

```
~
lsinitrd -f filename
```

For example, to output the contents of `sysctl.conf`, use the following command:

```
~
lsinitrd -f /etc/sysctl.conf
```

To specify a kernel version, use the `--kver` option:

```
~
lsinitrd --kver kernel_version -f /etc/sysctl.conf
```

For example, to list the information about kernel version 3.10.0-327.10.1.el7.x86_64, use the following command:

```
~
lsinitrd --kver 3.10.0-327.10.1.el7.x86_64 -f /etc/sysctl.conf
```
26.6. VERIFYING THE BOOT LOADER

When you install a kernel using `rpm`, the kernel package creates an entry in the boot loader configuration file for that new kernel. However, `rpm` does not configure the new kernel to boot as the default kernel. You must do this manually when installing a new kernel with `rpm`.

It is always recommended to double-check the boot loader configuration file after installing a new kernel with `rpm` to ensure that the configuration is correct. Otherwise, the system might not be able to boot into Red Hat Enterprise Linux properly. If this happens, boot the system with the boot media created earlier and re-configure the boot loader.
CHAPTER 27. WORKING WITH KERNEL MODULES

The Linux kernel is modular, which means it can extend its capabilities through the use of dynamically-loaded kernel modules. A kernel module can provide:

- a device driver which adds support for new hardware; or,
- support for a file system such as btrfs or NFS.

Like the kernel itself, modules can take parameters that customize their behavior, though the default parameters work well in most cases. User-space tools can list the modules currently loaded into a running kernel; query all available modules for available parameters and module-specific information; and load or unload (remove) modules dynamically into or from a running kernel. Many of these utilities, which are provided by the kmod package, take module dependencies into account when performing operations so that manual dependency-tracking is rarely necessary.

On modern systems, kernel modules are automatically loaded by various mechanisms when the conditions call for it. However, there are occasions when it is necessary to load or unload modules manually, such as when one module is preferred over another although either could provide basic functionality, or when a module is misbehaving.

This chapter explains how to:

- use the user-space kmod utilities to display, query, load and unload kernel modules and their dependencies;
- set module parameters both dynamically on the command line and permanently so that you can customize the behavior of your kernel modules; and,
- load modules at boot time.

NOTE

In order to use the kernel module utilities described in this chapter, first ensure the kmod package is installed on your system by running, as root:

```
~
```

```
$ yum install kmod
```

For more information on installing packages with Yum, see Section 8.2.4, “Installing Packages”.

27.1. LISTING CURRENTLY-LOADED MODULES

You can list all kernel modules that are currently loaded into the kernel by running the lsmod command, for example:

```
~
```

```
$ lsmod
```

<table>
<thead>
<tr>
<th>Module</th>
<th>Size</th>
<th>Used by</th>
</tr>
</thead>
<tbody>
<tr>
<td>tcp_lp</td>
<td>12663</td>
<td>0</td>
</tr>
<tr>
<td>bnet</td>
<td>19704</td>
<td>2</td>
</tr>
<tr>
<td>bluetooth</td>
<td>37266</td>
<td>7 bnet</td>
</tr>
<tr>
<td>rffkill</td>
<td>26536</td>
<td>3 bluetooth</td>
</tr>
<tr>
<td>fuse</td>
<td>87661</td>
<td>3</td>
</tr>
<tr>
<td>ip6t_rpfiler</td>
<td>12546</td>
<td>1</td>
</tr>
<tr>
<td>ip6t_REJECT</td>
<td>12939</td>
<td>2</td>
</tr>
</tbody>
</table>
Each row of `lsmod` output specifies:

- the name of a kernel module currently loaded in memory;
- the amount of memory it uses; and,
- the sum total of processes that are using the module and other modules which depend on it, followed by a list of the names of those modules, if there are any. Using this list, you can first unload all the modules depending the module you want to unload. For more information, see Section 27.4, “Unloading a Module”.

Finally, note that `lsmod` output is less verbose and considerably easier to read than the content of the `/proc/modules` pseudo-file.

## 27.2. DISPLAYING INFORMATION ABOUT A MODULE

You can display detailed information about a kernel module using the `modinfo module_name` command.

**NOTE**

When entering the name of a kernel module as an argument to one of the `kmod` utilities, do not append a `.ko` extension to the end of the name. Kernel module names do not have extensions; their corresponding files do.

**Example 27.1. Listing information about a kernel module with `lsmod`**
To display information about the e1000e module, which is the Intel PRO/1000 network driver, enter the following command as root:

```
~]# modinfo e1000e
```

**filename:** `/lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/net/ethernet/intel/e1000e/e1000e.ko`

**version:** `2.3.2-k`

**license:** GPL

**description:** Intel(R) PRO/1000 Network Driver

**author:** Intel Corporation, <linux.nics@intel.com>

**srcversion:** E9F7E754F6F3A1AD906634C

**alias:** pci:v00008086d000015A3sv*sd*bc*sc*i*

**alias:** pci:v00008086d000015A2sv*sd*bc*sc*i*

**depends:** ptp

**intree:** Y

**vermagic:** 3.10.0-121.el7.x86_64 SMP mod_unload modversions

**signer:** Red Hat Enterprise Linux kernel signing key

**sig_hashalgo:** sha256

**parm:** debug:Debug level (0=none,...,16=all) (int)

**parm:** copybreak:Maximum size of packet that is copied to a new buffer on receive (uint)

**parm:** TxIntDelay:Transmit Interrupt Delay (array of int)

**parm:** TxAbsIntDelay:Transmit Absolute Interrupt Delay (array of int)

**parm:** RxIntDelay:Receive Interrupt Delay (array of int)

**parm:** RxAbsIntDelay:Receive Absolute Interrupt Delay (array of int)

**parm:** InterruptThrottleRate:Interrupt Throttling Rate (array of int)

**parm:** IntMode:Interrupt Mode (array of int)

**parm:** SmartPowerDownEnable:Enable PHY smart power down (array of int)

**parm:** KumeranLockLoss:Enable Kumeran lock loss workaround (array of int)

**parm:** WriteProtectNVM:Write-protect NVM [WARNING: disabling this can lead to corrupted NVM] (array of int)

**parm:** CrcStripping:Enable CRC Stripping, disable if your BMC needs the CRC (array of int)

Here are descriptions of a few of the fields in `modinfo` output:

**filename**

The absolute path to the .ko kernel object file. You can use `modinfo -n` as a shortcut command for printing only the filename field.

**description**

A short description of the module. You can use `modinfo -d` as a shortcut command for printing only the description field.
alias

The alias field appears as many times as there are aliases for a module, or is omitted entirely if there are none.

depends

This field contains a comma-separated list of all the modules this module depends on.

NOTE

If a module has no dependencies, the depends field may be omitted from the output.

dparm

Each parm field presents one module parameter in the form parameter_name: description, where:

- parameter_name is the exact syntax you should use when using it as a module parameter on the command line, or in an option line in a .conf file in the /etc/modprobe.d/ directory; and,

- description is a brief explanation of what the parameter does, along with an expectation for the type of value the parameter accepts (such as int, unit or array of int) in parentheses.

Example 27.2. Listing module parameters

You can list all parameters that the module supports by using the -p option. However, because useful value type information is omitted from modinfo -p output, it is more useful to run:

~]# modinfo e1000e | grep "^parm" | sort
parm: copybreak: Maximum size of packet that is copied to a new buffer on receive (uint)
parm: CrcStripping: Enable CRC Stripping, disable if your BMC needs the CRC (array of int)
parm: debug: Debug level (0=None,...,16=all) (int)
parm: InterruptThrottleRate: Interrupt Throttling Rate (array of int)
parm: IntMode: Interrupt Mode (array of int)
parm: KumeranLockLoss: Enable Kumeran lock loss workaround (array of int)
parm: RxAbsIntDelay: Receive Absolute Interrupt Delay (array of int)
parm: RxIntDelay: Receive Interrupt Delay (array of int)
parm: SmartPowerDownEnable: Enable PHY smart power down (array of int)
parm: TxAbsIntDelay: Transmit Absolute Interrupt Delay (array of int)
parm: TxIntDelay: Transmit Interrupt Delay (array of int)
parm: WriteProtectNVM: Write-protect NVM [WARNING: disabling this can lead to corrupted NVM] (array of int)
27.3. LOADING A MODULE

To load a kernel module, run `modprobe module_name` as `root`. For example, to load the `wacom` module, run:

```
~]# modprobe wacom
```

By default, `modprobe` attempts to load the module from `/lib/modules/kernel_version/kernel/drivers/`. In this directory, each type of module has its own subdirectory, such as `net/` and `scsi/`, for network and SCSI interface drivers respectively.

Some modules have dependencies, which are other kernel modules that must be loaded before the module in question can be loaded. The `modprobe` command always takes dependencies into account when performing operations. When you ask `modprobe` to load a specific kernel module, it first examines the dependencies of that module, if there are any, and loads them if they are not already loaded into the kernel. `modprobe` resolves dependencies recursively: it will load all dependencies of dependencies, and so on, if necessary, thus ensuring that all dependencies are always met.

You can use the `-v` (or `--verbose`) option to cause `modprobe` to display detailed information about what it is doing, which can include loading module dependencies.

**Example 27.3. modprobe -v shows module dependencies as they are loaded**

You can load the Fibre Channel over Ethernet module verbosely by typing the following at a shell prompt:

```
~]# modprobe -v fcoe
insmod /lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/scsi/scsi_tgt.ko
insmod /lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/scsi/scsi_transport_fc.ko
insmod /lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/scsi/libfc/libfc.ko
insmod /lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/scsi/fcoe/libfcoe.ko
insmod /lib/modules/3.10.0-121.el7.x86_64/kernel/drivers/scsi/fcoe/fcoe.ko
```

In this example, you can see that `modprobe` loaded the `scsi_tgt`, `scsi_transport_fc`, `libfc` and `libfcoe` modules as dependencies before finally loading `fcoe`. Also note that `modprobe` used the more primitive `insmod` command to insert the modules into the running kernel.

**IMPORTANT**

Although the `insmod` command can also be used to load kernel modules, it does not resolve dependencies. Because of this, you should always load modules using `modprobe` instead.

27.4. UNLOADING A MODULE

You can unload a kernel module by running `modprobe -r module_name` as `root`. For example, assuming that the `wacom` module is already loaded into the kernel, you can unload it by running:
However, this command will fail if a process is using:

- the wacom module;
- a module that wacom directly depends on, or;
- any module that wacom, through the dependency tree, depends on indirectly.

See Section 27.1, “Listing Currently-Loaded Modules” for more information about using `lsmod` to obtain the names of the modules which are preventing you from unloading a certain module.

### Example 27.4. Unloading a kernel module

For example, if you want to unload the `firewire_ohci` module, your terminal session might look similar to this:

```
~]# modinfo -F depends firewire_ohci
  firewire-core
~]# modinfo -F depends firewire_core
  crc-itu-t
~]# modinfo -F depends crc-itu-t
```

You have figured out the dependency tree (which does not branch in this example) for the loaded Firewire modules: `firewire_ohci` depends on `firewire_core`, which itself depends on `crc-itu-t`.

You can unload `firewire_ohci` using the `modprobe -v -r module_name` command, where `-r` is short for `--remove` and `-v` for `--verbose`:

```
~]# modprobe -r -v firewire_ohci
rmmod firewire_ohci
rmmod firewire_core
rmmod crc_itu_t
```

The output shows that modules are unloaded in the reverse order that they are loaded, given that no processes depend on any of the modules being unloaded.

### IMPORTANT

Although the `rmmod` command can be used to unload kernel modules, it is recommended to use `modprobe -r` instead.

## 27.5. SETTING MODULE PARAMETERS

Like the kernel itself, modules can also take parameters that change their behavior. Most of the time, the default ones work well, but occasionally it is necessary or desirable to set custom parameters for a module. Because parameters cannot be dynamically set for a module that is already loaded into a running kernel, there are two different methods for setting them.
1. You can unload all dependencies of the module you want to set parameters for, unload the module using `modprobe -r`, and then load it with `modprobe` along with a list of customized parameters. This method is often used when the module does not have many dependencies, or to test different combinations of parameters without making them persistent, and is the method covered in this section.

2. Alternatively, you can list the new parameters in an existing or newly created file in the `/etc/modprobe.d/` directory. This method makes the module parameters persistent by ensuring that they are set each time the module is loaded, such as after every reboot or `modprobe` command. This method is covered in Section 27.6, “Persistent Module Loading”, though the following information is a prerequisite.

Example 27.5. Supplying optional parameters when loading a kernel module

You can use `modprobe` to load a kernel module with custom parameters using the following command line format:

```
~]$ modprobe module_name [parameter=value]
```

When loading a module with custom parameters on the command line, be aware of the following:

- You can enter multiple parameters and values by separating them with spaces.

- Some module parameters expect a list of comma-separated values as their argument. When entering the list of values, do not insert a space after each comma, or `modprobe` will incorrectly interpret the values following spaces as additional parameters.

- The `modprobe` command silently succeeds with an exit status of 0 if:
  - it successfully loads the module, or
  - the module is already loaded into the kernel.

Thus, you must ensure that the module is not already loaded before attempting to load it with custom parameters. The `modprobe` command does not automatically reload the module, or alert you that it is already loaded.

Here are the recommended steps for setting custom parameters and then loading a kernel module. This procedure illustrates the steps using the `e1000e` module, which is the network driver for Intel PRO/1000 network adapters, as an example:

Procedure 27.1. Loading a Kernel Module with Custom Parameters

1. First, ensure the module is not already loaded into the kernel:

```
~]$ lsmod |grep e1000e
```

Output would indicate that the module is already loaded into the kernel, in which case you must first unload it before proceeding. See Section 27.4, “Unloading a Module” for instructions on safely unloading it.

2. Load the module and list all custom parameters after the module name. For example, if you wanted to load the Intel PRO/1000 network driver with the interrupt throttle rate set to 3000
interrupts per second for the first, second, and third instances of the driver, and turn on debug, you would run, as root:

~]# modprobe e1000e InterruptThrottleRate=3000,3000,3000 debug=1

This example illustrates passing multiple values to a single parameter by separating them with commas and omitting any spaces between them.

### 27.6. PERSISTENT MODULE LOADING

As shown in Example 27.1, “Listing information about a kernel module with lsmod”, many kernel modules are loaded automatically at boot time. You can specify additional modules to be loaded by the systemctl-modules-load.service daemon by creating a program.conf file in the /etc/modules-load.d/ directory, where program is any descriptive name of your choice. The files in /etc/modules-load.d/ are text files that list the modules to be loaded, one per line.

**Example 27.6. A Text File to Load a Module**

To create a file to load the virtio-net.ko module, create a file /etc/modules-load.d/virtio-net.conf with the following content:

```
# Load virtio-net.ko at boot
virtio-net
```

See the modules-load.d(5) and systemctl-modules-load.service(8) man pages for more information.

### 27.7. INSTALLING MODULES FROM A DRIVER UPDATE DISK

Driver modules for hardware can be provided in the form of a driver update disk (DUD). The driver update disk, or an ISO image, is normally used at installation time to load and install any modules required for the hardware in use, and this process is described in the Red Hat Enterprise Linux 7 Installation Guide. However, if new driver modules are required after installation, use the following procedure. If you already have RPM files, go directly to step 5.

**Procedure 27.2. Installing New Modules from a Driver Update Disk**

Follow this post-installation procedure to install new driver modules from a driver update disk (DUD).

1. Install the driver update disk.

2. Create a mount point and mount the DUD. For example, as root:

   ~]# mkdir /run/OEMDRV
   ~]# mount -r -t iso9660 /dev/sr0 /run/OEMDRV

3. View the contents of the DUD. For example:

   ~]# ls /run/OEMDRV/
   rhdd3  rpms  src
4. Change into the directory relevant to the architecture of your system, contained within the `rpms/` directory, and list the contents. For example:

```bash
~]# cd /run/OEMDRV/rpms/x86_64/
~]# ls
kmod-bnx2x-1.710.51-3.el7_0.x86_64.rpm  kmod-bnx2x-firmware-1.710.51-3.el7_0.x86_64.rpm  repodata
```

In the above output the package version is `1.710.51` and the release is `3.el7_0`.

5. Install the RPM files simultaneously. For example:

```bash
~]# yum install kmod-bnx2x-1.710.51-3.el7_0.x86_64.rpm kmod-bnx2x-firmware-1.710.51-3.el7_0.x86_64.rpm
```

 Install 2 Packages

 Total size: 1.6 M
 Installed size: 1.6 M
 Is this ok [y/d/N]:

6. Enter the following command to make `depmod` probe all modules and update the list of dependencies:
7. Make a backup copy of the initial RAM file system by entering the following command:

```
-]# cp /boot/initramfs-$uname -r).img /boot/initramfs-$uname -r).img.$(date +%m-%d-%H%M%S).bak
```

8. Rebuild the initial RAM file system:

```
-]# dracut -f -v
```

9. To list the file contents of an initial RAM file system image created by dracut, enter a command as follows:

```
-]# lsinitrd /boot/initramfs-3.10.0-229.el7.x86_64.img
```

The output is very long, pipe the output through less or grep to find the module you are updating. For example:

```
-]# lsinitrd /boot/initramfs-3.10.0-229.el7.x86_64.img | grep bnx
```

```
drwxr-xr-x 2 root root 0 Jun 9 11:25 /usr/lib/firmware/bnx2x

27.8. SIGNING KERNEL MODULES FOR SECURE BOOT
Red Hat Enterprise Linux 7 includes support for the UEFI Secure Boot feature, which means that Red Hat Enterprise Linux 7 can be installed and run on systems where UEFI Secure Boot is enabled. Note that Red Hat Enterprise Linux 7 does not require the use of Secure Boot on UEFI systems.

When Secure Boot is enabled, the EFI operating system boot loaders, the Red Hat Enterprise Linux kernel, and all kernel modules must be signed with a private key and authenticated with the corresponding public key. The Red Hat Enterprise Linux 7 distribution includes signed boot loaders, signed kernels, and signed kernel modules. In addition, the signed first-stage boot loader and the signed kernel include embedded Red Hat public keys. These signed executable binaries and embedded keys enable Red Hat Enterprise Linux 7 to install, boot, and run with the Microsoft UEFI Secure Boot CA keys that are provided by the UEFI firmware on systems that support UEFI Secure Boot. Note that not all UEFI-based systems include support for Secure Boot.

The information provided in the following sections describes steps necessary to enable you to self-sign privately built kernel modules for use with Red Hat Enterprise Linux 7 on UEFI-based systems where Secure Boot is enabled. These sections also provide an overview of available options for getting your public key onto the target system where you want to deploy your kernel module.

### 27.8.1. Prerequisites

In order to enable signing of externally built modules, the tools listed in the following table are required to be installed on the system.

**Table 27.1. Required Tools**

<table>
<thead>
<tr>
<th>Tool</th>
<th>Provided by Package</th>
<th>Used on</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>openssl</td>
<td>openssl</td>
<td>Build system</td>
<td>Generates public and private X.509 key pair</td>
</tr>
<tr>
<td>sign-file</td>
<td>kernel-devel</td>
<td>Build system</td>
<td>Perl script used to sign kernel modules</td>
</tr>
<tr>
<td>perl</td>
<td>perl</td>
<td>Build system</td>
<td>Perl interpreter used to run the signing script</td>
</tr>
<tr>
<td>mokutil</td>
<td>mokutil</td>
<td>Target system</td>
<td>Optional tool used to manually enroll the public key</td>
</tr>
<tr>
<td>keyctl</td>
<td>keyutils</td>
<td>Target system</td>
<td>Optional tool used to display public keys in the system key ring</td>
</tr>
</tbody>
</table>

**NOTE**

Note that the build system, where you build and sign your kernel module, does not need to have UEFI Secure Boot enabled and does not even need to be a UEFI-based system.

### 27.8.2. Kernel Module Authentication
In Red Hat Enterprise Linux 7, when a kernel module is loaded, the module's signature is checked using the public X.509 keys on the kernel's system key ring, excluding those keys that are on the kernel's system black-list key ring.

### 27.8.2.1. Sources For Public Keys Used To Authenticate Kernel Modules

During boot, the kernel loads X.509 keys into the system key ring or the system black-list key ring from a set of persistent key stores as shown in Table 27.2, “Sources For System Key Rings”

#### Table 27.2. Sources For System Key Rings

<table>
<thead>
<tr>
<th>Source of X.509 Keys</th>
<th>User Ability to Add Keys</th>
<th>UEFI Secure Boot State</th>
<th>Keys Loaded During Boot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Embedded in kernel</td>
<td>No</td>
<td>-</td>
<td>.system_keyring</td>
</tr>
<tr>
<td>UEFI Secure Boot &quot;db&quot;</td>
<td>Limited</td>
<td>Not enabled</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>.system_keyring</td>
</tr>
<tr>
<td>UEFI Secure Boot &quot;dbx&quot;</td>
<td>Limited</td>
<td>Not enabled</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>.system_keyring</td>
</tr>
<tr>
<td>Embedded in shim.efi boot loader</td>
<td>No</td>
<td>Not enabled</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>.system_keyring</td>
</tr>
<tr>
<td>Machine Owner Key (MOK) list</td>
<td>Yes</td>
<td>Not enabled</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enabled</td>
<td>.system_keyring</td>
</tr>
</tbody>
</table>

Note that if the system is not UEFI-based or if UEFI Secure Boot is not enabled, then only the keys that are embedded in the kernel are loaded onto the system key ring and you have no ability to augment that set of keys without rebuilding the kernel. The system black list key ring is a list of X.509 keys which have been revoked. If your module is signed by a key on the black list then it will fail authentication even if your public key is in the system key ring.

You can display information about the keys on the system key rings using the `keyctl` utility. The following is abbreviated example output from a Red Hat Enterprise Linux 7 system where UEFI Secure Boot is not enabled.

```
~]# keyctl list %:.system_keyring
3 keys in keyring:
...asymmetric: Red Hat Enterprise Linux Driver Update Program (key 3):
bf57f3e87...
...asymmetric: Red Hat Enterprise Linux kernel signing key:
4249689ee8f7e5988080...
...asymmetric: Red Hat Enterprise Linux kpatch signing key:
4d38fd864e8e18c5f0b7...
```
The following is abbreviated example output from a Red Hat Enterprise Linux 7 system where UEFI Secure Boot is enabled.

```bash
[53x792]~]# keyctl list %:.system_keyring
6 keys in keyring:
...asymmetric: Red Hat Enterprise Linux Driver Update Program (key 3):
   bf57f3e87...
...asymmetric: Red Hat Secure Boot (CA key 1):
   401684164ce3a810408050766e8f8a29...
...asymmetric: Microsoft Corporation UEFI CA 2011:
   13adbf4309c8cd54f316ed...
...asymmetric: Microsoft Windows Production PCA 2011:
   a92902398e16c8788d90f99e...
...asymmetric: Red Hat Enterprise Linux kernel signing key:
   4249689eefc77e95880b...
...asymmetric: Red Hat Enterprise Linux kpatch signing key:
   4d38fd864ebe18c5f0b7...
```

The above output shows the addition of two keys from the UEFI Secure Boot "db" keys plus the Red Hat Secure Boot (CA key 1) which is embedded in the `shim.efi` boot loader. You can also look for the kernel console messages that identify the keys with an UEFI Secure Boot related source, that is UEFI Secure Boot db, embedded shim, and MOK list.

```bash
[53x735]~]# dmesg | grep 'EFI: Loaded cert'
[5.160660] EFI: Loaded cert 'Microsoft Windows Production PCA 2011: a9290239....
[5.160674] EFI: Loaded cert 'Microsoft Corporation UEFI CA 2011: 13adbf4309b....
[5.165794] EFI: Loaded cert 'Red Hat Secure Boot (CA key 1): 401684164ce3a8....
```

### 27.8.2.2. Kernel Module Authentication Requirements

If UEFI Secure Boot is enabled or if the `module.sig_enforce` kernel parameter has been specified, then only signed kernel modules that are authenticated using a key on the system key ring can be successfully loaded, provided that the public key is not on the system black list key ring. If UEFI Secure Boot is disabled and if the `module.sig_enforce` kernel parameter has not been specified, then unsigned kernel modules and signed kernel modules without a public key can be successfully loaded. This is summarized in Table 27.3, “Kernel Module Authentication Requirements for Loading”.

<table>
<thead>
<tr>
<th>Module Signed</th>
<th>Public Key Found and Signature Valid</th>
<th>UEFI Secure Boot State</th>
<th>module.sig_enforce</th>
<th>Module Load</th>
<th>Kernel Tainted</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unsigned</td>
<td>-</td>
<td>Not enabled</td>
<td>Not enabled</td>
<td>Succeeds</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>Not enabled</td>
<td>Enabled</td>
<td>Fails</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Enabled</td>
<td>-</td>
<td>Fails</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>
Subsequent sections will describe how to generate a public and private X.509 key pair, how to use the private key to sign a kernel module, and how to enroll the public key into a source for the system key ring.

27.8.3. Generating a Public and Private X.509 Key Pair

You need to generate a public and private X.509 key pair that will be used to sign a kernel module after it has been built. The corresponding public key will be used to authenticate the kernel module when it is loaded.

1. The openssl tool can be used to generate a key pair that satisfies the requirements for kernel module signing in Red Hat Enterprise Linux 7. Some of the parameters for this key generation request are best specified with a configuration file; follow the example below to create your own configuration file.

```bash
~]$ cat << EOF > configuration_file.config
[ req ]
default_bits = 4096
distinguished_name = req_distinguished_name
prompt = no
string_mask = utf8only
x509_extensions = myexts

[ req_distinguished_name ]
O = Organization
CN = Organization signing key
emailAddress = E-mail address

[ myexts ]
basicConstraints=critical,CA:FALSE
keyUsage=digitalSignature
subjectKeyIdentifier=hash
authorityKeyIdentifier=keyid
EOF
```
2. After you have created the configuration file, you can create an X.509 public and private key pair. The public key will be written to the `public_key.der` file and the private key will be written to the `private_key.priv` file.

```
~]# openssl req -x509 -new -nodes -utf8 -sha256 -days 36500 \
    -batch -config configuration_file.config -outform DER \
    -out public_key.der \
    -keyout private_key.priv
```

3. Enroll your public key on all systems where you want to authenticate and load your kernel module.

**WARNING**

Take proper care to guard the contents of your private key. In the wrong hands, the key could be used to compromise any system which has your public key.

### 27.8.4. Enrolling Public Key on Target System

When Red Hat Enterprise Linux 7 boots on a UEFI-based system with Secure Boot enabled, all keys that are in the Secure Boot db key database, but not in the dbx database of revoked keys, are loaded onto the system keyring by the kernel. The system keyring is used to authenticate kernel modules.

#### 27.8.4.1. Factory Firmware Image Including Public Key

To facilitate authentication of your kernel module on your systems, consider requesting your system vendor to incorporate your public key into the UEFI Secure Boot key database in their factory firmware image.

#### 27.8.4.2. Executable Key Enrollment Image Adding Public Key

It is possible to add a key to an existing populated and active Secure Boot key database. This can be done by writing and providing an EFI executable enrollment image. Such an enrollment image contains a properly formed request to append a key to the Secure Boot key database. This request must include data that is properly signed by the private key that corresponds to a public key that is already in the system's Secure Boot Key Exchange Key (KEK) database. Additionally, this EFI image must be signed by a private key that corresponds to a public key that is already in the key database.

It is also possible to write an enrollment image that runs under Red Hat Enterprise Linux 7. However, the Red Hat Enterprise Linux 7 image must be properly signed by a private key that corresponds to a public key that is already in the KEK database.

The construction of either type of key enrollment images requires assistance from the platform vendor.

#### 27.8.4.3. System Administrator Manually Adding Public Key to the MOK List

The Machine Owner Key (MOK) facility is a feature that is supported by Red Hat Enterprise Linux 7 and can be used to augment the UEFI Secure Boot key database. When Red Hat Enterprise Linux 7 boots on
a UEFI-enabled system with Secure Boot enabled, the keys on the MOK list are also added to the system keyring in addition to the keys from the key database. The MOK list keys are also stored persistently and securely in the same fashion as the Secure Boot key database keys, but these are two separate facilities. The MOK facility is supported by shim.efi, MokManager.efi, grubx64.efi, and the Red Hat Enterprise Linux 7 mokutil utility.

The major capability provided by the MOK facility is the ability to add public keys to the MOK list without needing to have the key chain back to another key that is already in the KEK database. However, enrolling a MOK key requires manual interaction by a physically present user at the UEFI system console on each target system. Nevertheless, the MOK facility provides an excellent method for testing newly generated key pairs and testing kernel modules signed with them.

Follow these steps to add your public key to the MOK list:

1. Request addition of your public key to the MOK list using a Red Hat Enterprise Linux 7 user space utility:

   ```
   ~]# mokutil --import my_signing_key_pub.der
   ```

   You will be asked to enter and confirm a password for this MOK enrollment request.

2. Reboot the machine.

3. The pending MOK key enrollment request will be noticed by shim.efi and it will launch MokManager.efi to allow you to complete the enrollment from the UEFI console. You will need to enter the password you previously associated with this request and confirm the enrollment. Your public key is added to the MOK list, which is persistent.

Once a key is on the MOK list, it will be automatically propagated to the system key ring on this and subsequent boots when UEFI Secure Boot is enabled.

27.8.5. Signing Kernel Module with the Private Key

There are no extra steps required to prepare your kernel module for signing. You build your kernel module normally. Assuming an appropriate Makefile and corresponding sources, follow these steps to build your module and sign it:

1. Build your my_module.ko module the standard way:

   ```
   ~]# make -C /usr/src/kernels/$(uname -r) M=$PWD modules
   ```

2. Sign your kernel module with your private key. Note that you need to provide both the files that contain your private and the public key as well as the kernel module file that you want to sign.

   ```
   ~]#/usr/src/kernels/$(uname -r)/scripts/sign-file \ 
   sha256 \ 
   my_signing_key.priv \ 
   my_signing_key_pub.der \ 
   my_module.ko
   ```

   Your kernel module is in ELF image format and this script computes and appends the signature directly to the ELF image in your my_module.ko file. The modinfo utility can be used to display information about the kernel module's signature, if it is present. For information on using the utility, see
Section 27.2, “Displaying Information About a Module”.

Note that this appended signature is not contained in an ELF image section and is not a formal part of the ELF image. Therefore, tools such as readelf will not be able to display the signature on your kernel module.

Your kernel module is now ready for loading. Note that your signed kernel module is also loadable on systems where UEFI Secure Boot is disabled or on a non-UEFI system. That means you do not need to provide both a signed and unsigned version of your kernel module.

27.8.6. Loading Signed Kernel Module

Once your public key is enrolled and is in the system keyring, the normal kernel module loading mechanisms will work transparently. In the following example, you will use mokutil to add your public key to the MOK list and you will manually load your kernel module with modprobe.

1. Optionally, you can verify that your kernel module will not load before you have enrolled your public key. First, verify what keys have been added to the system key ring on the current boot by running the keyctl list %:.system_keyring as root. Since your public key has not been enrolled yet, it should not be displayed in the output of the command.

2. Request enrollment of your public key.

   ~ ]# mokutil --import my_signing_key_pub.der

3. Reboot, and complete the enrollment at the UEFI console.

   ~ ]# reboot

4. After the system reboots, verify the keys on the system key ring again.

   ~ ]# keyctl list %:.system_keyring

5. You should now be able to load your kernel module successfully.

   ~ ]# modprobe -v my_module
   insmod /lib/modules/3.10.0-123.el7.x86_64/extra/my_module.ko
   ~ ]# lsmod | grep my_module
   my_module 12425 0

27.9. ADDITIONAL RESOURCES

For more information on kernel modules and their utilities, see the following resources.

Manual Page Documentation

- lsmod(8) – The manual page for the lsmod command.
- modinfo(8) – The manual page for the modinfo command.
- modprobe(8) – The manual page for the modprobe command.
- rmmod(8) – The manual page for the rmmod command.
- **ethtool(8)** – The manual page for the `ethtool` command.
- **mii-tool(8)** – The manual page for the `mii-tool` command.

Installable and External Documentation

- **/usr/share/doc/kernel-doc-kernel_version/Documentation/** – This directory, which is provided by the kernel-doc package, contains information on the kernel, kernel modules, and their respective parameters. Before accessing the kernel documentation, you must run the following command as root:

```
~]# yum install kernel-doc
```

- **Linux Loadable Kernel Module HOWTO** – The *Linux Loadable Kernel Module HOWTO* from the Linux Documentation Project contains further information on working with kernel modules.
PART VIII. SYSTEM BACKUP AND RECOVERY

This part describes how to use the Relax-and-Recover (ReaR) disaster recovery and system migration utility.
CHAPTER 28. RELAX-AND-RECOVER (REAR)

When a software or hardware failure breaks the system, the system administrator faces three tasks to restore it to the fully functioning state on a new hardware environment:

1. booting a rescue system on the new hardware
2. replicating the original storage layout
3. restoring user and system files

Most backup software solves only the third problem. To solve the first and second problems, use Relax-and-Recover (ReaR), a disaster recovery and system migration utility.

Backup software creates backups. ReaR complements backup software by creating a rescue system. Booting the rescue system on a new hardware allows you to issue the `rear recover` command, which starts the recovery process. During this process, ReaR replicates the partition layout and filesystems, prompts for restoring user and system files from the backup created by backup software, and finally installs the boot loader. By default, the rescue system created by ReaR only restores the storage layout and the boot loader, but not the actual user and system files.

This chapter describes how to use ReaR.

28.1. BASIC REAR USAGE

28.1.1. Installing ReaR

Install the `rear` package and its dependencies by running the following command as root:

```
~]# yum install rear genisoimage syslinux
```

28.1.2. Configuring ReaR

ReaR is configured in the `/etc/rear/local.conf` file. Specify the rescue system configuration by adding these lines:

```
OUTPUT=output format
OUTPUT_URL=output location
```

Substitute `output format` with rescue system format, for example, `ISO` for an ISO disk image or `USB` for a bootable USB.

Substitute `output location` with where it will be put, for example, `file:///mnt/rescue_system/` for a local filesystem directory or `sftp://backup:password@192.168.0.0/` for an SFTP directory.

Example 28.1. Configuring Rescue System Format and Location

To configure ReaR to output the rescue system as an ISO image into the `/mnt/rescue_system/` directory, add these lines to the `/etc/rear/local.conf` file:

```
OUTPUT=ISO
OUTPUT_URL=file:///mnt/rescue_system/
```
See section "Rescue Image Configuration" of the rear(8) man page for a list of all options.

ISO-specific Configuration
Using the configuration in Example 28.1, “Configuring Rescue System Format and Location” results into two equivalent output files in two locations:

- `/var/lib/rear/output/` - rear's default output location
- `/mnt/rescue_system/HOSTNAME/rear-localhost.iso` - output location specified in `OUTPUT_URL`

However, usually you need only one ISO image. To make ReaR create an ISO image only in the directory specified by a user, add these lines to `/etc/rear/local.conf`:

```
OUTPUT=ISO
BACKUP=NETFS
OUTPUT_URL=null
BACKUP_URL="iso:///backup"
ISO_DIR="output location"
```

Substitute `output location` with the desired location for the output.

28.1.3. Creating a Rescue System

The following example shows how to create a rescue system with verbose output:

```
-]# rear -v mkrescue
Relax-and-Recover 1.17.2 / Git
Using log file: /var/log/rear/rear-rhel7.log
mkdir: created directory '/var/lib/rear/output'
Creating disk layout
Creating root filesystem layout
TIP: To login as root via ssh you need to set up
/root/.ssh/authorized_keys or SSH_ROOT_PASSWORD in your configuration file
Copying files and directories
Copying binaries and libraries
Copying kernel modules
Creating initramfs
Making ISO image
Wrote ISO image: /var/lib/rear/output/rear-rhel7.iso (124M)
Copying resulting files to file location
```

With the configuration from Example 28.1, “Configuring Rescue System Format and Location”, ReaR prints the above output. The last two lines confirm that the rescue system has been successfully created and copied to the configured backup location `/mnt/rescue_system/`. Because the system's host name is `rhel7`, the backup location now contains directory `rhel7/` with the rescue system and auxiliary files:

```
-]# ls -lh /mnt/rescue_system/rhel7/
total 124M
-rw--------. 1 root root 202 Jun 10 15:27 README
```
Transfer the rescue system to an external medium to not lose it in case of a disaster.

### 28.1.4. Scheduling ReaR

To schedule ReaR to regularly create a rescue system using the `cron` job scheduler, add the following line to the `/etc/crontab` file:

```
minute hour day_of_month month day_of_week root /usr/sbin/rear mkrescue
```

Substitute the above command with the cron time specification (described in detail in Section 22.1.2, “Scheduling a Cron Job”).

#### Example 28.2. Scheduling ReaR

To make ReaR create a rescue system at 22:00 every weekday, add this line to the `/etc/crontab` file:

```
0 22 * * 1-5 root /usr/sbin/rear mkrescue
```

### 28.1.5. Performing a System Rescue

To perform a restore or migration:

1. Boot the rescue system on the new hardware. For example, burn the ISO image to a DVD and boot from the DVD.

2. In the console interface, select the "Recover" option:

![Figure 28.1. Rescue system: menu](image)
3. You are taken to the prompt:

```bash
RESCUE rhel7:~ #
```

**Figure 28.2. Rescue system: prompt**

**WARNING**

Once you have started recovery in the next step, it probably cannot be undone and you may lose anything stored on the physical disks of the system.

4. Run the `rear recover` command to perform the restore or migration. The rescue system then recreates the partition layout and filesystems:
5. Restore user and system files from the backup into the `/mnt/local/` directory.

**Example 28.3. Restoring User and System Files**

In this example, the backup file is a tar archive created per instructions in Section 28.2.1.1, “Configuring the Internal Backup Method”. First, copy the archive from its storage, then unpack the files into `/mnt/local/`, then delete the archive:

```bash
~# scp root@192.168.122.7:/srv/backup/rhel7/backup.tar.gz /mnt/local/
~# tar xf /mnt/local/backup.tar.gz -C /mnt/local/
~# rm -f /mnt/local/backup.tar.gz
```
The new storage has to have enough space both for the archive and the extracted files.

6. Verify that the files have been restored:

   ~]# ls /mnt/local/

   Disk layout created.
   Please start the restore process on your backup host.

   Make sure that you restore the data into '/mnt/local' instead of '/' because the hard disks of the recovered system are mounted there.

   Please restore your backup in the provided shell and, when finished, type exit in the shell to continue recovery.

   rear> scp root@192.160.122.7:/srv/backup/rhel7/backup.tar.gz /mnt/local/
   The authenticity of host '192.160.122.7' (192.160.122.7)' can't be established.
   ECDSA key fingerprint is c9:a4:f2:89:f0:ef:3a:6b:bb:1b:b1:b7:08:f0:dd:1c.
   Are you sure you want to continue connecting (yes/no)? yes
   Warning: Permanently added '192.160.122.7' (ECDSA) to the list of known hosts.
   root@192.160.122.7's password:
   backup.tar.gz
   rear> tar xf /mnt/local/backup.tar.gz -C /mnt/local/
   rear> rm -f /mnt/local/backup.tar.gz
   rear> ls /mnt/local/
   bin boot dev etc home lib lib64 media mnt opt proc root run sbin
   sys tmp usr var
   rear> ~

   Figure 28.4. Rescue system: restoring user and system files from the backup

7. Ensure that SELinux relabels the files on the next boot:

   ~]# touch /mnt/local/.autorelabel

   Otherwise you may be unable to log in the system, because the /etc/passwd file may have the incorrect SELinux context.

8. Finish the recovery by entering exit. ReaR will then reinstall the boot loader. After that, reboot the system:
Upon reboot, SELinux will relabel the whole filesystem. Then you will be able to log in to the recovered system.

28.2. INTEGRATING REAR WITH BACKUP SOFTWARE

The main purpose of ReaR is to produce a rescue system, but it can also be integrated with backup software. What integration means is different for the built-in, supported, and unsupported backup methods.

28.2.1. The Built-in Backup Method

ReaR ships with a built-in, or internal, backup method. This method is fully integrated with ReaR, which has these advantages:

- a rescue system and a full-system backup can be created using a single `rear mkbackup` command
- the rescue system restores files from the backup automatically

As a result, ReaR can cover the whole process of creating both the rescue system and the full-system backup.

28.2.1.1. Configuring the Internal Backup Method

To make ReaR use its internal backup method, add these lines to `/etc/rear/local.conf`:

```
BACKUP=NETFS
BACKUP_URL=backup location
```
These lines configure ReaR to create an archive with a full-system backup using the `tar` command. Substitute `backup location` with one of the options from the "Backup Software Integration" section of the `rear(8)` man page. Make sure that the backup location has enough space.

**Example 28.4. Adding tar Backups**

To expand the example in Section 28.1, “Basic ReaR Usage”, configure ReaR to also output a `tar` full-system backup into the `/srv/backup/` directory:

```plaintext
OUTPUT=ISO
OUTPUT_URL=file:///mnt/rescue_system/
BACKUP=NETFS
BACKUP_URL=file:///srv/backup/
```

The internal backup method allows further configuration.

- To keep old backup archives when new ones are created, add this line:
  ```plaintext
  NETFS_KEEP_OLD_BACKUP_COPY=y
  ```

- By default, ReaR creates a full backup on each run. To make the backups incremental, meaning that only the changed files are backed up on each run, add this line:
  ```plaintext
  BACKUP_TYPE=incremental
  ```
  This automatically sets `NETFS_KEEP_OLD_BACKUP_COPY` to `y`.

- To ensure that a full backup is done regularly in addition to incremental backups, add this line:
  ```plaintext
  FULLBACKUPDAY="Day"
  ```
  Substitute "Day" with one of the "Mon", "Tue", "Wed", "Thu", "Fri", "Sat", "Sun".

- ReaR can also include both the rescue system and the backup in the ISO image. To achieve this, set the `BACKUP_URL` directive to `iso:///backup/`.

  ```plaintext
  BACKUP_URL=iso:///backup/
  ```

  This is the simplest method of full-system backup, because the rescue system does not need the user to fetch the backup during recovery. However, it needs more storage. Also, single-ISO backups cannot be incremental.

**Example 28.5. Configuring Single-ISO Rescue System and Backups**

This configuration creates a rescue system and a backup file as a single ISO image and puts it into the `/srv/backup/` directory:

```plaintext
OUTPUT=ISO
OUTPUT_URL=file:///srv/backup/
BACKUP=NETFS
BACKUP_URL=iso:///backup/
```
NOTE

The ISO image might be large in this scenario. Therefore, Red Hat recommends creating only one ISO image, not two. For details, see the section called “ISO-specific Configuration”.

- To use rsync instead of tar, add this line:
  
  ```
  BACKUP_PROG=rsync
  ```

  Note that incremental backups are only supported when using tar.

28.2.1.2. Creating a Backup Using the Internal Backup Method

With BACKUP=NETFS set, ReaR can create either a rescue system, a backup file, or both.

- To create a rescue system only, run:
  
  ```
  rear mkrescue
  ```

- To create a backup only, run:
  
  ```
  rear mkbackuponly
  ```

- To create a rescue system and a backup, run:
  
  ```
  rear mkbackup
  ```

Note that triggering backup with ReaR is only possible if using the NETFS method. ReaR cannot trigger other backup methods.

NOTE

When restoring, the rescue system created with the BACKUP=NETFS setting expects the backup to be present before executing `rear recover`. Hence, once the rescue system boots, copy the backup file into the directory specified in BACKUP_URL, unless using a single ISO image. Only then run `rear recover`.

To avoid recreating the rescue system unnecessarily, you can check whether storage layout has changed since the last rescue system was created using these commands:

```bash
~]$ rear checklayout
~]$ echo $?
```

Non-zero status indicates a change in disk layout. Non-zero status is also returned if ReaR configuration has changed.
IMPORTANT

The `rear checklayout` command does not check whether a rescue system is currently present in the output location, and can return 0 even if it is not there. So it does not guarantee that a rescue system is available, only that the layout has not changed since the last rescue system has been created.

Example 28.6. Using `rear checklayout`

To create a rescue system, but only if the layout has changed, use this command:

```bash
~]# rear checklayout || rear mkrescue
```

28.2.2. Supported Backup Methods

In addition to the NETFS internal backup method, ReaR supports several external backup methods. This means that the rescue system restores files from the backup automatically, but the backup creation cannot be triggered using ReaR.

For a list and configuration options of the supported external backup methods, see the "Backup Software Integration" section of the `rear(8)` man page.

28.2.3. Unsupported Backup Methods

With unsupported backup methods, there are two options:

1. The rescue system prompts the user to manually restore the files. This scenario is the one described in "Basic ReaR Usage", except for the backup file format, which may take a different form than a `tar` archive.

2. ReaR executes the custom commands provided by the user. To configure this, set the `BACKUP` directive to `EXTERNAL`. Then specify the commands to be run during backing up and restoration using the `EXTERNAL_BACKUP` and `EXTERNAL_RESTORE` directives. Optionally, also specify the `EXTERNAL_IGNORE_ERRORS` and `EXTERNAL_CHECK` directives. See `/usr/share/rear/conf/default.conf` for an example configuration.

28.2.4. Creating Multiple Backups

With the version 2.00, ReaR supports creation of multiple backups. Backup methods that support this feature are:

- `BACKUP=NETFS` (internal method)
- `BACKUP=BORG` (external method)

You can specify individual backups with the `-C` option of the `rear` command. The argument is a basename of the additional backup configuration file in the `/etc/rear/` directory. The method, destination, and the options for each specific backup are defined in the specific configuration file, not in the main configuration file.

To perform the basic recovery of the system:
Procedure 28.1. Basic recovery of the system

1. Create the ReaR recovery system ISO image together with a backup of the files of the basic system:

   ```
   ~> rear -C basic_system mkbackup
   ```

2. Back the files up in the /home directories:

   ```
   ~> rear -C home_backup mkbackuponly
   ```

Note that the specified configuration file should contain the directories needed for a basic recovery of the system, such as /boot, /root, and /usr.

Procedure 28.2. Recovery of the system in the rear recovery shell

To recover the system in the rear recovery shell, use the following sequence of commands:

1. ```
   ~> rear -C basic_system recover
   ```

2. ```
   ~> rear -C home_backup restoreonly
   ```
APPENDIX A. RPM

The RPM Package Manager (RPM) is an open packaging system that runs on Red Hat Enterprise Linux as well as other Linux and UNIX systems. Red Hat and the Fedora Project encourage other vendors to use RPM for their own products. RPM is distributed under the terms of the GPL (GNU General Public License).

The RPM Package Manager only works with packages built in the RPM format. RPM itself is provided as the pre-installed rpm package. For the end user, RPM makes system updates easy. Installing, uninstalling, and upgrading RPM packages can be accomplished with short commands. RPM maintains a database of installed packages and their files, so you can invoke powerful queries and verifications on your system. There are several applications, such as Yum or PackageKit, that can make working with packages in the RPM format even easier.

WARNING

For most package-management tasks, the Yum package manager offers equal and often greater capabilities and utility than RPM. Yum also performs and tracks complicated system-dependency resolutions. Yum maintains the system integrity and forces a system integrity check if packages are installed or removed using another application, such as RPM, instead of Yum. For these reasons, it is highly recommended that you use Yum instead of RPM whenever possible to perform package-management tasks. See Chapter 8, Yum.

If you prefer a graphical interface, you can use the PackageKit GUI application, which uses Yum as its back end, to manage your system's packages.

During upgrades, RPM handles configuration files carefully, so that you never lose your customizations — something that you cannot accomplish with regular .tar.gz files.

For the developer, RPM enables software source code to be packaged into source and binary packages for end users. This process is quite simple and is driven from a single file and optional patches that you create. This clear delineation between pristine sources and your patches along with build instructions eases the maintenance of the package as new versions of the software are released.

NOTE

Because RPM can make changes to the system itself, performing operations like installing, upgrading, downgrading, and uninstalling binary packages system-wide requires root privileges in most cases.

A.1. RPM DESIGN GOALS

To understand how to use RPM, it is helpful to understand the design goals of RPM:

Upgradability

With RPM, you can upgrade individual components of your system without a complete reinstallation. When you get a new release of an operating system based on RPM, such as Red Hat Enterprise Linux, you do not need to reinstall a fresh copy of the operating system on your machine.
RPM allows for intelligent, fully-automated, in-place upgrades of your system. In addition, configuration files in packages are preserved across upgrades, so you do not lose your customizations. There are no special upgrade files needed to upgrade a package because the same RPM file is used to both install and upgrade the package on the system.

**Powerful Querying**

RPM is designed to provide powerful querying options. You can perform searches on your copy of the database for packages or even just certain files. You can also easily find out what package a file belongs to and where the package came from. The files an RPM package contains are in a compressed archive, with a custom binary header containing useful information about the package and its contents, allowing you to query individual packages quickly and easily.

**System Verification**

Another powerful RPM feature is the ability to verify packages. It allows you to verify that the files installed on the system are the same as the ones supplied by a given package. If an inconsistency is detected, RPM notifies you, and you can reinstall the package if necessary. Any configuration files that you modified are preserved during reinstallation.

**Pristine Sources**

A crucial design goal was to allow the use of pristine software sources, as distributed by the original authors of the software. With RPM, you have the pristine sources along with any patches that were used, plus complete build instructions. This is an important advantage for several reasons. For example, if a new version of a program is released, you do not necessarily have to start from scratch to get it to compile. You can look at the patch to see what you might need to do. All the compiled-in defaults, and all of the changes that were made to get the software to build properly, are easily visible using this technique.

The goal of keeping sources pristine may seem important only for developers, but it results in higher quality software for end users.

### A.2. USING RPM

RPM has five basic modes of operation (excluding package building): installing, uninstalling, upgrading, querying, and verifying. This section contains an overview of each mode. For complete details and options, try `rpm --help` or see `rpm(8)`. Also, see Section A.5, “Additional Resources” for more information on RPM.

#### A.2.1. Installing and Upgrading Packages

RPM packages typically have file names in the following form:

```
package_name-version-release-operating_system-CPU_architecture.rpm
```

For example, the `tree-1.6.0-10.el7.x86_64.rpm` file name includes the package name (tree), version (1.6.0), release (10), operating system major version (el7) and CPU architecture (x86_64).
IMPORTANT

When installing a package, ensure it is compatible with your operating system and processor architecture. This can usually be determined by checking the package name. For example, the file name of an RPM package compiled for the AMD64/Intel 64 computer architectures ends with x86_64.rpm.

The `-U` (or `--upgrade`) option has two functions, it can be used to:

- upgrade an existing package on the system to a newer version, or
- install a package if an older version is not already installed.

The `rpm -U package.rpm` command is therefore able to either `upgrade` or `install`, depending on the presence of an older version of `package.rpm` on the system.

Assuming the `tree-1.6.0-10.el7.x86_64.rpm` package is in the current directory, log in as `root` and type the following command at a shell prompt to either upgrade or install the `tree` package:

```
~# rpm -Uvh tree-1.6.0-10.el7.x86_64.rpm
```

The `-v` and `-h` options (which are combined with `-U`) cause `rpm` to print a more verbose output and display a progress meter using hash signs. If the upgrade or installation is successful, the following output is displayed:

```
Preparing...                 ################################# [100%]
Updating / installing...     ################################# [100%]
1:tree-1.6.0-10.el7          ################################# [100%]
```

**WARNING**

`rpm` provides two different options for installing packages: the aforementioned `-U` option (which historically stands for `upgrade`), and the `-i` option (which historically stands for `install`). Because the `-U` option includes both install and upgrade functions, the use of `rpm -Uvh` with all packages, except kernel packages, is recommended.

You should always use the `-i` option to `install` a new kernel package instead of upgrading it. This is because using the `-U` option to upgrade a kernel package removes the previous (older) kernel package, which could render the system unable to boot if there is a problem with the new kernel. Therefore, use the `rpm -i kernel_package` command to install a new kernel without replacing any older kernel packages. For more information on installing kernel packages, see Chapter 26, Manually Upgrading the Kernel.

The signature of a package is checked automatically when installing or upgrading a package. The signature confirms that the package was signed by an authorized party. If the verification of the signature fails, an error message is displayed.
If you do not have the appropriate key installed to verify the signature, the message contains the word NOKEY:

```
warning: tree-1.6.0-10.el7.x86_64.rpm: Header V3 RSA/SHA256 Signature, key ID 431d51: NOKEY
```

See Section A.3.2, “Checking Package Signatures” for more information on checking package signatures.

### A.2.1.1. Replacing Already Installed Packages

If a package of the same name and version is already installed, the following output is displayed:

```
Preparing... #............................................................
[100%]
package tree-1.6.0-10.el7.x86_64 is already installed
```

To install the package anyway, use the `--replacepkgs` option, which tells RPM to ignore the error:

```
~]# rpm -Uvh --replacepkgs tree-1.6.0-10.el7.x86_64.rpm
```

This option is helpful if files installed from the package were deleted or if you want the original configuration files to be installed.

If you attempt an upgrade to an older version of a package (that is, if a newer version of the package is already installed), RPM informs you that a newer version is already installed. To force RPM to perform the downgrade, use the `--oldpackage` option:

```
rpm -Uvh --oldpackage older_package.rpm
```

### A.2.1.2. Resolving File Conflicts

If you attempt to install a package that contains a file that has already been installed by another package, a conflict message is displayed. To make RPM ignore this error, use the `--replacefiles` option:

```
rpm -Uvh --replacefiles package.rpm
```

### A.2.1.3. Satisfying Unresolved Dependencies

RPM packages sometimes depend on other packages, which means that they require other packages to be installed to run properly. If you try to install a package that has an unresolved dependency, a message about a failed dependency is displayed.

Find the suggested package(s) on the Red Hat Enterprise Linux installation media or on one of the active Red Hat Enterprise Linux mirrors and add it to the installation command. To determine which package contains the required file, use the `--whatprovides` option:

```
rpm -q --whatprovides "required_file"
```

If the package that contains `required_file` is in the RPM database, the name of the package is displayed.
A.2.1.4. Preserving Changes in Configuration Files

Because RPM performs intelligent upgrading of packages with configuration files, you may see the following message:

```
saving /etc/configuration_file.conf as /etc/configuration_file.conf.rpmsave
```

This message means that the changes you made to the configuration file may not be forward-compatible with the new configuration file in the package, so RPM saved your original file and installed a new one. You should investigate the differences between the two configuration files and resolve them as soon as possible to ensure that your system continues to function properly.

Alternatively, RPM may save the package's new configuration file as, for example, `configuration_file.conf.rpmnew` and leave the configuration file you modified untouched. You should still resolve any conflicts between your modified configuration file and the new one, usually by merging changes from the old one to the new one, for example using the `diff` program.

A.2.2. Uninstalling Packages

Uninstalling a package is just as simple as installing one. Type the following command at a shell prompt as `root`:

```
rpm -e package
```

**NOTE**

Note that the command expects only the package name, not the name of the original package file. If you attempt to uninstall a package using the `rpm -e` command and provide the original full file name, you receive a package name error.

You can encounter dependency errors when uninstalling a package if another installed package depends on the one you are trying to remove. For example:

```
[1]# rpm -e ghostscript
error: Failed dependencies:
  ghostscript is needed by (installed) ghostscript-cups-9.07-
WARNING

Although you can force rpm to uninstall a package that has unresolved dependencies (using the --nodeps option), this is not recommended. Removing packages with --nodeps can cause applications from the packages whose dependencies are removed to misbehave or terminate unexpectedly. It can also cause serious package-management problems or system failure. For these reasons, heed the warnings about failed dependencies.

A.2.3. Freshening Packages

Freshening is similar to upgrading, except that only installed packages are upgraded. Type the following command at a shell prompt as root:

```
rpm -Fvh package.rpm
```

The -F (or --freshen) option compares the versions of the packages specified on the command line with the versions of packages that are already installed on the system. When a newer version of an already installed package is processed by the --freshen option, it is upgraded to the newer version. However, the --freshen option does not install a package if no previously installed package of the same name exists. This differs from regular upgrading, as an upgrade installs all specified packages regardless of whether or not older versions of the packages are already installed.

Freshening works for single packages or package groups. For example, freshening can help if you download a large number of different packages, and you only want to upgrade those packages that are already installed on the system. In this case, issue the following command with the *.rpm global expression:

```
~]# rpm -Fvh *.rpm
```

RPM then automatically upgrades only those packages that are already installed.

A.2.4. Querying Packages

The RPM database stores information about all RPM packages installed on the system. It is stored in the /var/lib/rpm/ directory and is used for many things, including querying what packages are installed, what version each package is, and for calculating changes to files in packages since their installation. To query this database, use the rpm command with the -q (or --query) option:
rpm -q package_name

This command displays the package name, version, and release number of the installed package package_name. For example:

~]\$ rpm -q tree
tree-1.6.0-10.el7.x86_64

See the Package Selection Options subheading in the rpm(8) manual page for a list of options that can be used to further refine or qualify your query. Use options listed below the Package Query Options subheading to specify what information to display about the queried packages.

A.2.5. Verifying Packages

Verifying a package is comparing information about files on the system installed from a package with the same information from the original package. Among other parameters, verifying compares the file size, MD5 sum, permissions, type, owner, and the group of each file.

Use the rpm command with the -V (or --verify) option to verify packages. For example:

~]\$ rpm -V tree

See the Package Selection Options subheading in the rpm(8) manual page for a list of options that can be used to further refine or qualify your query. Use options listed below the Verify Options subheading to specify what characteristics to verify in the queried packages.

If everything verifies properly, there is no output. If there are any discrepancies, they are displayed. The output consists of lines similar to these:

~]\# rpm -V abrt
S.5....T.  c /etc/abrt/abrt.conf
.M.......  /var/spool/abrt-upload

The format of the output is a string of nine characters followed by an optional attribute marker and the name of the processed file.

The first nine characters are the results of tests performed on the file. Each test is the comparison of one attribute of the file to the value of that attribute as recorded in the RPM database. A single period (.) means the test passed, and the question-mark character (?) signifies that the test could not be performed. The following table lists symbols that denote specific discrepancies:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>file size differs</td>
</tr>
<tr>
<td>M</td>
<td>mode differs (includes permissions and file type)</td>
</tr>
<tr>
<td>S</td>
<td>digest (formerly MD5 sum) differs</td>
</tr>
<tr>
<td>D</td>
<td>device major/minor number mismatch</td>
</tr>
</tbody>
</table>
### Symbol Description

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>readLink(2) path mismatch</td>
</tr>
<tr>
<td>U</td>
<td>user ownership differs</td>
</tr>
<tr>
<td>G</td>
<td>group ownership differs</td>
</tr>
<tr>
<td>T</td>
<td>mtime differs</td>
</tr>
<tr>
<td>P</td>
<td>capabilities differ</td>
</tr>
</tbody>
</table>

The attribute marker, if present, describes the purpose of the given file. The following table lists the available attribute markers:

**Table A.2. RPM Verification Symbols**

<table>
<thead>
<tr>
<th>Marker</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>configuration file</td>
</tr>
<tr>
<td>d</td>
<td>documentation file</td>
</tr>
<tr>

If you see any output, use your best judgment to determine if you should remove the package, reinstall it, or fix the problem in another way.

### A.3. FINDING AND VERIFYING RPM PACKAGES

Before using any RPM packages, you must know where to find them and be able to verify if you can trust them.

#### A.3.1. Finding RPM Packages

Although there are many RPM repositories on the Internet, for security and compatibility reasons, you should consider installing only official Red Hat-provided RPM packages. The following is a list of sources for RPM packages:

- Official Red Hat Enterprise Linux installation media.
- Official RPM repositories provided with the *Yum* package manager. See [Chapter 8, *Yum*](#) for details on how to use the official Red Hat Enterprise Linux package repositories.

Extra Packages for Enterprise Linux (EPEL) is a community effort to provide a repository with high-quality add-on packages for Red Hat Enterprise Linux. See http://fedoraproject.org/wiki/EPEL for details on EPEL RPM packages.

Unofficial, third-party repositories not affiliated with Red Hat also provide RPM packages.

**IMPORTANT**

When considering third-party repositories for use with your Red Hat Enterprise Linux system, pay close attention to the repository's web site with regard to package compatibility before adding the repository as a package source. Alternate package repositories may offer different, incompatible versions of the same software, including packages already included in the Red Hat Enterprise Linux repositories.

### A.3.2. Checking Package Signatures

RPM packages can be signed using GNU Privacy Guard (or GPG), which helps you make certain that downloaded packages are trustworthy. GPG is a tool for secure communication. With GPG, you can authenticate the validity of documents and encrypt or decrypt data.

To verify that a package has not been corrupted or tampered with, check its GPG signature by using the `rpmkeys` command with the `-K` (or `--checksig`) option:

```
rpmkeys -K package.rpm
```

Note that the Yum package manager performs automatic checking of GPG signatures during installations and upgrades.

GPG is installed by default, as well as a set of Red Hat keys for verifying packages. To import additional keys for use with RPM, see Section A.3.2.1, “Importing GPG Keys”.

### A.3.2.1. Importing GPG Keys

To verify Red Hat packages, a Red Hat GPG key needs to be installed. A set of basic keys is installed by default. To view a list of installed keys, execute the following command at a shell prompt:

```
$ rpm -qa gpg-pubkey*
```

To display details about a specific key, use `rpm -qi` followed by the output from the previous command. For example:

```
$ rpm -qi gpg-pubkey-fd431d51-4ae0493b
```

Use the `rpmkeys` command with the `--import` option to install a new key for use with RPM. The default location for storing RPM GPG keys is the `/etc/pki/rpm-gpg/` directory. To import new keys, use a command like the following as root:

```
$ rpmkeys --import /etc/pki/rpm-gpg/RPM-GPG-KEY-redhat-release
```
See the Product Signing (GPG) Keys article on the Red Hat Customer Portal for additional information about Red Hat package-signing practices.

A.4. COMMON EXAMPLES OF RPM USAGE

RPM is a useful tool for both managing your system and diagnosing and fixing problems. See the following examples for an overview of some of the most-used options.

- To verify your entire system and see what files are missing, issue the following command as root:

```
rpm -Va
```

If some files are missing or appear corrupted, consider reinstalling relevant packages.

- To determine which package owns a file, enter:

```
rpm -qf file
```

- To verify the package that owns a particular file, enter as root:

```
rpm -Vf file
```

- To locate documentation files that are a part of a package to which a file belongs, enter:

```
rpm -qdf file
```

- To find information about a (non-installed) package file, use the following command:

```
rpm -qip package.rpm
```

- To list files contained in a package, use:

```
rpm -qlp package.rpm
```

See the rpm(8) manual page for more options.

A.5. ADDITIONAL RESOURCES

RPM is a complex utility with many options and methods for querying, installing, upgrading, and removing packages. See the following resources to learn more about RPM.

**Installed Documentation**

- `rpm --help` – This command displays a quick reference of RPM parameters.
- `rpm(8)` – The RPM manual page offers an overview of all available RPM parameters.

**Online Documentation**

- The RPM mailing list — [http://lists.rpm.org/mailman/listinfo/rpm-list](http://lists.rpm.org/mailman/listinfo/rpm-list)

**See Also**

- Chapter 8, *Yum* describes how to use the Yum package manager to search, install, update, and uninstall packages on the command line.
APPENDIX B. CHOOSING SUITABLE RED HAT PRODUCT

A Red Hat Cloud Infrastructure or Red Hat Cloud Suite subscription provides access to multiple Red Hat products with complementary feature sets.

To determine products appropriate for your organization and use case, you can use Cloud Deployment Planner (CDP). CDP is an interactive tool which summarizes specific interoperability and feature compatibility considerations across various product releases.

To compare supportability of specific features and compatibility of various products depending on Red Hat Enterprise Linux version, see comprehensive compatibility matrix.
APPENDIX C. RED HAT CUSTOMER PORTAL LABS RELEVANT TO SYSTEM ADMINISTRATION

Red Hat Customer Portal Labs are tools designed to help you improve performance, troubleshoot issues, identify security problems, and optimize configuration. This appendix provides an overview of Red Hat Customer Portal relevant to system administration. All Red Hat Customer Portal Labs are available at Customer Portal Labs.

ISCSI HELPER
The iSCSI Helper provides a block-level storage over Internet Protocol (IP) networks, and enables the use of storage pools within server virtualization.

Use the iSCSI Helper to generate a script that prepares the system for its role of an iSCSI target (server) or an iSCSI initiator (client) configured according to the settings that you provide.

NTP CONFIGURATION
Use the NTP (Network Time Protocol) Configuration to set up:

- servers running the NTP service
- clients synchronized with NTP servers

SAMBA CONFIGURATION HELPER
The Samba Configuration Helper creates a configuration that provides basic file and printer sharing through Samba:

- Click Server to specify basic server settings.
- Click Shares to add the directories that you want to share
- Click Server to add attached printers individually.

VNC CONFIGURATOR
The VNC Configurator is designed to install and configure VNC (Virtual Network Computing) server on a Red Hat Enterprise Linux server.

Use the VNC Configurator to generate all-in-one script optimized to install and configure the VNC service on your Red Hat Enterprise Linux server.

BRIDGE CONFIGURATION
The Bridge Configuration is designed to configure a bridged network interface for applications such as KVM using Red Hat Enterprise Linux 5.4 or later.

NETWORK BONDING HELPER
The Network Bonding Helper allows administrators to bind multiple Network Interface Controllers together into a single channel using the bonding kernel module and the bonding network interface.

Use the Network Bonding Helper to enable two or more network interfaces to act as one bonding interface.

LVM RAID CALCULATOR
The LVM RAID Calculator determines the optimal parameters for creating logical volumes (LVMs) on a given RAID storage after you specify storage options.
Use the LVM RAID Calculator to generate a sequence of commands that create LVMs on a given RAID storage.

**NFS HELPER**
The NFS Helper simplifies configuring a new NFS server or client. Follow the steps to specify the export and mount options. Then, generate a downloadable NFS configuration script.

**LOAD BALANCER CONFIGURATION TOOL**
The Load Balancer Configuration Tool creates an optimal balance between apache-based load balancers and JBoss/Tomcat application servers.

Use the Load Balancer Configuration Tool to generate a configuration file and advice about how you can increase the performance of your environment.

**YUM REPOSITORY CONFIGURATION HELPER**
The Yum Repository Configuration Helper is designed to set up a simple Yum repository.

Use the Yum Repository Configuration Helper to set up:

- a local Yum repository
- a HTTP/FTP-based Yum repository

**FILE SYSTEM LAYOUT CALCULATOR**
The File System Layout Calculator determines the optimal parameters for creating ext3, ext4, and xfs file systems, after you provide storage options that describe your current or planned storage.

Use the File System Layout Calculator to generate a command that creates a file system with provided parameters on the specified RAID storage.

**RHEL BACKUP AND RESTORE ASSISTANT**
The RHEL Backup and Restore Assistant provides information on back-up and restore tools, and common scenarios of Linux usage.

Described tools:

- dump and restore: for backing up the ext2, ext3, and ext4 file systems.
- tar and cpio: for archiving or restoring files and folders, especially when backing up the tape drives.
- rsync: for performing back-up operations and synchronizing files and directories between locations.
- dd: for copying files from a source to a destination block by block independently of the file systems or operating systems involved.

Described scenarios:

- Disaster recovery
- Hardware migration
- Partition table backup
- Important folder backup
- Incremental backup
- Differential backup

**DNS HELPER**
The DNS Helper provides assistance with configuring different types of DNS servers.

Use the DNS Helper to generate a bash script to automatically create and configure the DNS server.

**AD INTEGRATION HELPER (SAMBA FS - WINBIND)**
The AD Integration Helper is used for connecting Samba File System server to an Active Directory (AD) server.

Use AD Integration Helper to generate a script based on basic AD server information supplied by the user. The generated script configures Samba, Name Service Switch (NSS) and Pluggable Authentication Module (PAM).

**RED HAT ENTERPRISE LINUX UPGRADE HELPER**
The Red Hat Enterprise Linux Upgrade Helper is designed to help you with upgrading Red Hat Enterprise Linux from version 6.5/6.6/6.7/6.8 to version 7.x.

**REGISTRATION ASSISTANT**
The Registration Assistant is designed to help you choose the most suitable registration option for your Red Hat Enterprise Linux environment.

**RESCUE MODE ASSISTANT**
The Rescue Mode Assistant is designed to help you solve the following problems in the rescue mode of Red Hat Enterprise Linux:

- Reset root password
- Generate a SOS report
- Perform a Filesystem Check (fsck)
- Reinstall GRUB
- Rebuild the Initial Ramdisk Image
- Reduce the size of the root file system

**KERNEL OOPS ANALYZER**
The Kernel Oops Analyzer is designed to help you with solving a kernel crash.

Use the Kernel Oops Analyzer to input a text or a file including one or more kernel oops messages and find a solution suitable for your case.

**KDUMP HELPER**
The Kdump Helper is designed to set up the Kdump mechanism.

Use the Kdump Helper to generate a script to set up Kdump to dump data in memory into a dump file called a vmcore.

**SCSI DECODER**
The **SCSI decoder** is designed to decode SCSI error messages in the `/log/*` files or log file snippets, as these error messages can be hard to understand for the user.

Use the **SCSI decoder** to individually diagnose each SCSI error message and get solutions to resolve problems efficiently.

**RED HAT MEMORY ANALYZER**
The **Red Hat Memory Analyzer** visualizes memory usage on your system based on information captured by the SAR utility.

**MULTIPATH HELPER**
The **Multipath Helper** creates an optimal configuration for multipath devices on Red Hat Enterprise Linux 5, 6, and 7.

Use the **Multipath Helper** to create advanced multipath configurations, such as custom aliases or device blacklists.

The Multipath Helper also provides the `multipath.conf` file for a review. When you achieve the required configuration, download the installation script to run on your server.

**MULTIPATH CONFIGURATION VISUALIZER**
The **Multipath Configuration Visualizer** analyzes the files in a SOS report and provides a diagram that visualizes the multipath configuration. Use the **Multipath Configuration Visualizer** to display:

- Hosts components including Host Bus Adapters (HBAs), local devices, and iSCSI devices on the server side
- Storage components on the storage side
- Fabric or Ethernet components between the server and the storage
- Paths to all mentioned components

You can either upload a SOS report compressed in the .xz, .gz, or .bz2 format, or extract a SOS report in a directory that you then select as the source for a client-side analysis.

**RED HAT I/O USAGE VISUALIZER**
The **Red Hat I/O Usage Visualizer** displays a visualization of the I/O device usage statistics captured by the SAR utility.

**STORAGE / LVM CONFIGURATION VIEWER**
The **Storage / LVM configuration viewer** analyzes the files included in a SOS report and creates a diagram to visualize the Storage/LVM configuration.
APPENDIX D. REVISION HISTORY

Revision 0.14-17  Tue Dec 5 2017  Marie Doleželová
Updated Samba section. Added section about Configuring RELP with TLS. Updated section on Upgrading from GRUB Legacy to GRUB 2.

Revision 0.14-16  Mon Aug 8 2017  Marie Doleželová
Minor fixes throughout the guide, added links to articles dealing with choosing a target for ordering and dependencies of the custom unit files to the chapter "Creating Custom Unit Files".

Revision 0.14-14  Thu Jul 27 2017  Marie Doleželová
Document version for 7.4 GA publication.

Revision 0.14-13  Thu Jul 27 2017  Marie Doleželová
Document version for 7.4 GA publication.

Revision 0.14-12  Tue Jul 25 2017  Marie Doleželová
Document version for 7.4 GA publication.

Revision 0.14-11  Tue Jul 25 2017  Marie Doleželová
Document version for 7.4 GA publication.

Revision 0.14-8  Mon Nov 3 2016  Maxim Svistunov
Version for 7.3 GA publication.

Revision 0.14-7  Mon Jun 20 2016  Maxim Svistunov
Added Relax-and-Recover (ReaR); made minor improvements.

Revision 0.14-6  Thu Mar 10 2016  Maxim Svistunov
Minor fixes and updates.

Revision 0.14-5  Thu Jan 21 2016  Lenka Špačková
Minor factual updates.

Revision 0.14-3  Wed Nov 11 2015  Jana Heves
Version for 7.2 GA release.

Revision 0.14-1  Mon Nov 9 2015  Jana Heves
Minor fixes, added links to RH training courses.

Revision 0.14-0.3  Fri Apr 3 2015  Stephen Wadeley
Added Registering the System and Managing Subscriptions, Accessing Support Using the Red Hat Support Tool, updated Viewing and Managing Log Files.

Revision 0.13-2  Tue Feb 24 2015  Stephen Wadeley
Version for 7.1 GA release.

Revision 0.12-0.6  Tue Nov 18 2014  Stephen Wadeley
Improved TigerVNC.

Revision 0.12-0.4  Mon Nov 10 2014  Stephen Wadeley
Improved Yum, Managing Services with systemd, OpenLDAP, Viewing and Managing Log Files, OProfile, and Working with the GRUB 2 Boot Loader.

Revision 0.12-0  Tue 19 Aug 2014  Stephen Wadeley
Red Hat Enterprise Linux 7.0 GA release of the System Administrator's Guide.
D.1. ACKNOWLEDGMENTS

S

Samba
  Samba Printers, Adding a Samba (SMB) printer

scp (see OpenSSH)
security plug-in (see Security)

Security-Related Packages
  updating security-related packages, Updating Packages

Sendmail, Sendmail
  additional resources, Additional Resources
  aliases, Masquerading
  common configuration changes, Common Sendmail Configuration Changes
  default installation, The Default Sendmail Installation
  LDAP and, Using Sendmail with LDAP
  limitations, Purpose and Limitations
  masquerading, Masquerading
  purpose, Purpose and Limitations
  spam, Stopping Spam
  with UUCP, Common Sendmail Configuration Changes

sendmail, Mail Transport Agent (MTA) Configuration

setfacl, Setting Access ACLs

sftp (see OpenSSH)

shadow passwords
  overview of, Shadow Passwords

SpamAssassin
  using with Procmail, Spam Filters

ssh (see OpenSSH)

SSH protocol
  authentication, Authentication

configuration files, Configuration Files
  system-wide configuration files, Configuration Files
  user-specific configuration files, Configuration Files

connection sequence, Event Sequence of an SSH Connection

features, Main Features

insecure protocols, Requiring SSH for Remote Connections

layers
  channels, Channels
transport layer, Transport Layer
port forwarding, Port Forwarding
requiring for remote login, Requiring SSH for Remote Connections
security risks, Why Use SSH?
version 1, Protocol Versions
version 2, Protocol Versions
X11 forwarding, X11 Forwarding

ssh-add, Configuring ssh-agent
ssh-agent, Configuring ssh-agent
SSL, Setting Up an SSL Server
   (see also Apache HTTP Server)
SSL server (see Apache HTTP Server)
star, Archiving File Systems With ACLs
stunnel, Securing Email Client Communications
subscriptions, Registering the System and Managing Subscriptions
system analysis
   OProfile (see OProfile)

system information
   cpu usage, Viewing CPU Usage
   file systems, Viewing Block Devices and File Systems
   gathering, System Monitoring Tools
   hardware, Viewing Hardware Information
   memory usage, Viewing Memory Usage
   processes, Viewing System Processes
      currently running, Using the top Command

System Log
   filtering, Viewing Log Files
   monitoring, Monitoring Log Files
   refresh rate, Viewing Log Files
   searching, Viewing Log Files

System Monitor, Using the System Monitor Tool, Using the System Monitor Tool, Using the System Monitor Tool, Using the System Monitor Tool
systems
   registration, Registering the System and Managing Subscriptions
   subscription management, Registering the System and Managing Subscriptions

T
the Users settings tool (see user configuration)
TLS , Setting Up an SSL Server
(see also Apache HTTP Server )

top, Using the top Command

U
user configuration
command line configuration
  passwd, Adding a New User
  useradd, Adding a New User

viewing list of users, Managing Users in a Graphical Environment

user private groups (see groups)
  and shared directories, Creating Group Directories

useradd command
  user account creation using, Adding a New User

users (see user configuration)
  additional resources, Additional Resources
    installed documentation, Additional Resources

  installing, Managing Users and Groups
  tools for management of
    the Users setting tool, Using Command-Line Tools
    useradd, Using Command-Line Tools

  UID, Managing Users and Groups

V
virtual host (see Apache HTTP Server )
vsftpd
  additional resources, Additional Resources
    installed documentation, Installed Documentation
    online documentation, Online Documentation

  encrypting, Encrypting vsftpd Connections Using TLS
  multihome configuration, Starting Multiple Copies of vsftpd
  restarting, Starting and Stopping vsftpd
  securing, Encrypting vsftpd Connections Using TLS, SELinux Policy for vsftpd
  SELinux, SELinux Policy for vsftpd
  starting, Starting and Stopping vsftpd
  starting multiple copies of, Starting Multiple Copies of vsftpd
status, Starting and Stopping vsftpd
stopping, Starting and Stopping vsftpd
TLS, Encrypting vsftpd Connections Using TLS

W
web server (see Apache HTTP Server)

Y
Yum
configuring plug-ins, Enabling, Configuring, and Disabling Yum Plug-ins
configuring yum and yum repositories, Configuring Yum and Yum Repositories
disabling plug-ins, Enabling, Configuring, and Disabling Yum Plug-ins
displaying packages
  yum info, Displaying Package Information
displaying packages with yum
